## Introduction

Fermat's earliest interest in number theory grew out of the classical concept of a perfect number, one equal to the sum of all its proper divisors. Book IX of Euclid's Elements contains a proof that if $2^{n}-1$ is prime, then $2^{n-1} \cdot\left(2^{n}-1\right)$ is perfect. The Greeks had, however, only been able to discover four perfect numbers, $6,28,496$ and 8128 , because it was difficult to determine the values of $n$ for which $2^{n}-1$ is prime. Fermat discovered three propositions that could help in this regard, propositions he communicated to Mersenne in a letter of June 1640. The first of these results was that if $n$ is not itself prime, then $2^{n}-1$ cannot be prime. The proof of this result just exhibited the factors: If $n=r \cdot s$, then

$$
2^{n}-1=2^{r \cdot s}-1=\left(2^{r}-1\right)\left(2^{r(s-1)}+2^{r(s-2)}+\cdots+2^{r}+1\right)
$$

The basic question therefore reduced to asking for which primes $p$ is $2^{p}-1$ prime. Such primes are today called Mersenne primes in honor of Fermat's favorite correspondent (I have quoted this from [Katz] page 458).

Definition 0.1 Let $l \in \mathbb{N}$. The number $2^{l}-1$ will be denoted by $M_{l}$. If $M_{l}$ is prime we shall call $M_{l}$ a Mersenne prime.

The biggest known prime at the moment (March 2002) is the Mersenne prime $2^{13466917}-1$. It is no coincidence that the biggest known prime at the moment is a Mersenne prime, because there is a very easy test, the Lucas-Lehmer test (see [Beukers] page 44), to check whether a number of the form $2^{p}-1$ is prime or not.

David A. Cox has written a book about primes of the form $x^{2}+d \cdot y^{2}$ (see [Cox]). In this paper we consider this for Mersenne primes, so the fundamental equation of this paper is

$$
\begin{equation*}
M_{l}=x^{2}+d \cdot y^{2}, \tag{0.1}
\end{equation*}
$$

with $x, y, d \in \mathbb{Z}_{>0}$ and $M_{l}$ a Mersenne prime.
Definition 0.2 We define $F_{d}$ to be the quadratic form $X^{2}+d \cdot Y^{2} \in \mathbb{Z}[X, Y]$. Let $p$ be a prime. We shall say that $p$ is represented by $F_{d}$ if there is a tuple $(x, y) \in \mathbb{Z}_{\geq 0}^{2}$ such that $p=x^{2}+d \cdot y^{2}$.

Proposition 0.3 Let $M_{l}$ be a Mersenne prime. Let $d \in \mathbb{Z}_{>0}$. Suppose that $F_{d}$ represents $M_{l}$. Then there is a unique tuple $(x, y) \in \mathbb{Z}_{\geq 0}^{2}$ with the property $M_{l}=x^{2}+d \cdot y^{2}$.

## Proof:

If $d=0$ then clearly $F_{d}$ does not represent $M_{l}$. If $d=1$ then $x^{2}+d \cdot y^{2} \equiv 1 \bmod 4$, but since we have $M_{l} \equiv 3 \bmod 4$, we see that $F_{d}$ does not represent $M_{l}$. Let $d>1$. We know that $M_{l} \neq 2$. If $M_{l} \mid d$ then $F_{d}$ does not represent $M_{l}$ or $M_{l}=d$. In the last case it is clear that $(x, y)=(0,1)$ is the unique tuple
in $\mathbb{Z}_{\geq 0}^{2}$ with $M_{l}=x^{2}+d \cdot y^{2}$. Now we may assume that $M_{l} \nmid 2 d$. But then $M_{l}$ does not divide the conductor $f$ of $\mathbb{Z}[\sqrt{-d}]$, because $f$ obeys the relation $-4 d=f^{2} \Delta(\mathbb{Q}(\sqrt{-d}) / \mathbb{Q})$. Suppose that $(x, y)$ and $\left(x^{\prime}, y^{\prime}\right)$ are tuples in $\mathbb{Z}_{>0}^{2}$ with the property that $M_{l}=x^{2}+d \cdot y^{2}=\left(x^{\prime}\right)^{2}+d \cdot\left(y^{\prime}\right)^{2}$. Since $M_{l}$ does not divide $f$ we know that $M_{l}$ splits uniquely in two principal prime ideals in $\mathbb{Z}[\sqrt{-d}]$ (see [Cox] page 144), so we have that the element $x^{\prime}+y^{\prime} \sqrt{-d}$ is equal to, let's say, the element $(x+y \sqrt{-d}) \cdot u$ for a certain $u \in \mathbb{Z}[\sqrt{-d}]^{*}=\{ \pm 1\}$. We get $x=x^{\prime} u$, hence $x=x^{\prime}$. Therefore we have $(x, y)=\left(x^{\prime}, y^{\prime}\right)$. This completes the proof.

Definition 0.4 We call the unique tuple $(x, y)$ in proposition (0.3) the $F_{d^{-}}$solution of $M_{l}$.

We will be concerned with two questions. The first most natural question to arise is: Can we decide for a given $d \in \mathbb{Z}_{>0}$ and a given Mersenne prime $M_{l}$ whether or not $F_{d}$ represents $M_{l}$ ? Suppose $F_{d}$ represents $M_{l}$. Let $(x, y)$ be the $F_{d}$-solution of $M_{l}$. Our second question is: What can we say about the divisibility of $x$ or $y$ by small primes ( 2 or 3 )?

An illustration of both questions, which was implicitly the start of this paper, is the following table made by Franz Lemmermeyer.

$$
\begin{aligned}
& 2^{7}-1=127=8^{2}+7 \cdot 3^{2} \\
& 2^{13}-1=8191=48^{2}+7 \cdot 29^{2} \\
& 2^{19}-1=524287=720^{2}+7 \cdot 29^{2} \\
& 2^{31}-1=2147483647=43968^{2}+7 \cdot 5533^{2} \\
& 2^{61}-1=2305843009213693951=910810592^{2}+7 \cdot 459233379^{2}
\end{aligned}
$$

In this table we see the first few nontrivial solutions of the equation $M_{l}=$ $x^{2}+7 \cdot y^{2}$. Franz Lemmermeyer observed that $x$ is divisible by 8 every time. That this is true in general was proved by Hendrik Lenstra and Peter Stevenhagen (see [LenSte]). The idea they used in the proof of their theorem can be generalized. One generalization leads to the following result.

Theorem 0.5 Let $d=2^{n}-1$ be a squarefree integer with $2 \nmid n$. Let $M_{l}$ be a Mersenne prime with $l \equiv 1 \bmod n$. Suppose that $(x, y)$ is the $F_{d}$-solution of $M_{l}$ then $8 \mid x$.

Definition 0.6 Let $0<n<38$ be an integer. We define $A_{n}$ be the set of the first $n$ Mersenne primes. We define $s_{n}(d)$ to be $\left\{M_{l} \in A_{n} \mid F_{d}\right.$ represents $\left.M_{l}\right\}$.

This paper is divided in four chapters. In the first chapter we will look at the $F_{d}$-solution of $M_{l}$ for $M_{l} \in s_{10}(d)$ and $d$ between 0 and 48, and we will look at the numbers $\# s_{20}(d)$ for $d$ between 0 and 48 . We will observe some structure in our examples. Some of these structures are easy to prove, see proposition (1.1), and some are harder to prove, see for example proposition (3.6). In chapter two we will state a couple of theorems we use in chapter three and four. Keywords in chapter two are the Artin map, Hilbert class field, ray class field and ring class field. These class fields will help us to decide whether or not $F_{d}$ represents $M_{l}$.

The knowledge of chapter two will be used to explain the numbers \#s $s_{20}(d)$ we found in chapter one. Take for example $d=14$. We get for this $d$ the following nice result. Suppose that $M_{l}$ is a Mersenne prime then

$$
F_{14} \text { represents } M_{l} \Leftrightarrow l \equiv 1 \bmod 3 .
$$

The technique we used to prove the above statement will also be used in the proof of theorem (0.5) in chapter four.

I would like to thank my supervisor Bart de Smit and Peter Stevenhagen for their advice and suggestions.

## Chapter 1

## Numerical results

In this chapter we will look at the $F_{d}$-solution of $M_{l}$ for $M_{l} \in s_{10}(d)$ and $d$ between 0 and 48, and we will look at the numbers $\# s_{20}(d)$ for $d$ between 0 and 48.

In Pari/GP, the well known computer algebra package (see [Cohen2] page 525), one can implement the algorithm of Cornacchia (see [Beukers] page 157 or [Cohen] page 34) to calculate the $F_{d}$-solution of $M_{l}$. The first ten Mersenne primes are $M_{2}, M_{3}, M_{5}, M_{7}, M_{13}, M_{17}, M_{19}, M_{31}, M_{61}$ and $M_{89}$. The $F_{d}$-solution of $M_{l}$ for $M_{l} \in s_{10}(d)$ and $d$ between 0 and 48 are given below.
$d=2$
$M_{2}=(1)^{2}+2 \cdot(1)^{2}$
$d=3$
$M_{2}=(0)^{2}+3 \cdot(1)^{2}$
$M_{3}=(2)^{2}+3 \cdot(1)^{2}$
$M_{5}=(2)^{2}+3 \cdot(3)^{2}$
$M_{7}=(2 \cdot 5)^{2}+3 \cdot(3)^{2}$
$M_{13}=(2 \cdot 23)^{2}+3 \cdot\left(3^{2} \cdot 5\right)^{2}$
$M_{17}=(2 \cdot 181)^{2}+3 \cdot(3)^{2}$
$M_{19}=(2 \cdot 149)^{2}+3 \cdot(3 \cdot 127)^{2}$
$M_{31}=(2 \cdot 23081)^{2}+3 \cdot\left(3^{4} \cdot 29\right)^{2}$
$M_{61}=(2 \cdot 9697 \cdot 77617)^{2}+3 \cdot\left(3^{2} \cdot 11 \cdot 13 \cdot 89611\right)^{2}$
$M_{89}=(2 \cdot 601 \cdot 14456661997)^{2}+3 \cdot\left(3 \cdot 5^{3} \cdot 1979 \cdot 13851631\right)^{2}$
$d=6$
$M_{3}=(1)^{2}+6 \cdot(1)^{2}$
$M_{5}=(5)^{2}+6 \cdot(1)^{2}$
$M_{7}=(11)^{2}+6 \cdot(1)^{2}$
$M_{13}=(29)^{2}+6 \cdot(5 \cdot 7)^{2}$
$M_{17}=(5 \cdot 71)^{2}+6 \cdot(29)^{2}$
$M_{19}=(349)^{2}+6 \cdot(7 \cdot 37)^{2}$

```
\(M_{31}=(44029)^{2}+6 \cdot(3 \cdot 7 \cdot 281)^{2}\)
\(M_{61}=(47 \cdot 1321 \cdot 22027)^{2}+6 \cdot(5 \cdot 7 \cdot 7697863)^{2}\)
\(M_{89}=(7 \cdot 43 \cdot 77508521119)^{2}+6 \cdot(5 \cdot 173 \cdot 11087 \cdot 367867)^{2}\)
\(d=7\)

```

Some $d$ 's give a lot of solutions, for example $d=3,6,27$, other $d$ 's a few and there are also a lot of $d$ 's without a solution. Now take a look at the divisibility of $x$ or $y$ by 2 or 3 . For example take $d=3$ then most $y$ 's are divisible by 3 . For $d=15$ we see that $4 \mid x$. The proposition below explains some of these observations. We will explain the other observations in chapter three.

Proposition 1.1 Let $M_{l} \neq 3$ be a Mersenne prime. If $d \equiv 0,1,2,4,5 \bmod 8$ then $F_{d}$ does not represent $M_{l}$. Suppose that $F_{d}$ represents $M_{l}$. Let $(x, y)$ be the $F_{d}$-solution of $M_{l}$. For the remaining cases of $d \bmod 8$ we have the following properties:

| $d \bmod 8$ | properties of $(x, y)$ |
| :---: | :---: |
| 3 | $2 \\| x$ |
| 6 | $2 \nmid x \cdot y$ |
| 7 | $4 \mid x$ |

For the cases $d \equiv 1,2 \bmod 3$ we have the following properties:

| $d \bmod 3$ | properties of $(x, y)$ |
| :---: | :---: |
| 1 | either $3 \mid x$ or $3 \mid y$ |
| 2 | $3 \mid y$ |

## Proof:

Since we assumed that $M_{l} \neq 3$ we have $M_{l} \equiv-1 \bmod 8$. Because a square modulo 8 equals $0,1,4 \bmod 8$, we see from the equivalence $M_{l} \equiv-1 \equiv x^{2}+$ $d \cdot y^{2} \bmod 8$, after we have checked all the possible combinations, that we have no solutions for $d \equiv 0,1,2,4,5 \bmod 8$. For $d \equiv 3 \bmod 8$ we see that $2 \| x$. If $d \equiv 6 \bmod 8$ then $2 \nmid x \cdot y$. And for $d \equiv 7 \bmod 8$ we see that $4 \mid x$. Suppose that $d \equiv 1 \bmod 3$, then $M_{l} \equiv 1 \equiv x^{2}+d \cdot y^{2} \equiv x^{2}+y^{2} \bmod 3$, so either $3 \mid x$ or $3 \mid y$. Suppose $d \equiv 2 \bmod 3$ then $M_{l} \equiv 1 \equiv x^{2}+d \cdot y^{2} \equiv x^{2}-y^{2} \bmod 3$, so $3 \mid y$. This completes the proof.

With proposition (1.1) we can exclude $d \equiv 0,1,2,4,5 \bmod 8$, if $d \neq 2$. For the case $d=2$ we know by proposition (1.1) that $F_{2}$ represents $M_{l}$ if and only if $M_{l}=3=1^{2}+2 \cdot 1^{2}$. In the table below we see the numbers $\# s_{20}(d)$ for each $d$ between 0 and 48 .

| $d$ | 2 | 3 | 6 | 7 | 11 | 14 | 15 | 19 | 22 | 23 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\# s_{20}(d)$ | 1 | 20 | 19 | 13 | 1 | 12 | 9 | 2 | 8 | 2 |

| $d$ | 27 | 30 | 31 | 35 | 38 | 39 | 43 | 46 | 47 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\# s_{20}(d)$ | 18 | 9 | 5 | 0 | 2 | 7 | 3 | 6 | 1 |

For $d=3,7,15$ we see that $\left|\# s_{20}(d)-\# s_{20}(2 d)\right| \leq 1$. In chapter three we will prove for these $d$ 's that if $M_{l}$ is a Mersenne prime not equal to $d$ then $F_{d}$ represents $M_{l}$ if and only if $F_{2 d}$ represents $M_{l}$. In chapter three we will find criteria to decide whether or not $F_{d}$ represents $M_{l}$, for $d$ between 0 and 48. With these criteria we can explain the numbers $\# s_{20}(d)$ in the table above.

Let's take a look again at the $F_{d}$-solution of $M_{l}$ for $M_{l} \in s_{10}(d)$ and $d$ between 0 and 48, with the divisibility of $x$ by 8 for $d=7$ in mind. For $d=15$ we already mentioned that $4 \mid x$. Now $7=2^{3}-1$ and $15=2^{4}-1$. The next odd power of two minus one is $2^{5}-1=31$ and if we check the divisibility of $x$ by 2 for $d=31$, we see that for our two nontrivial solutions we both have $8 \mid x$. The next $M_{l}$ such that $F_{31}$ represents $M_{l}$ is $M_{521}$ and also $8 \mid x$. After $M_{521}$ the next two $M_{l}$ 's with $F_{31}$ represents $M_{l}$ are $M_{4253}$ and $M_{11213}$. But for both $F_{31}$-solutions $(x, y)$ of $M_{4253}$ and $(x, y)$ of $M_{11213}$ we have $8 \nmid x$. Next we have $2^{7}-1=127$. The first nontrivial Mersenne prime $M_{l}$ such that $F_{127}$ represents $M_{l}$ is $M_{127}$.
$M_{127}=12831216340765303000^{2}+127 \cdot 208123802438146401^{2}$
The next one is $M_{9689}$. For both $F_{127}$-solutions $(x, y)$ of $M_{127}$ and $(x, y)$ of $M_{9689}$ we have $8 \mid x$. I did not found Mersenne primes which are represented
by $F_{2^{9}-1}$ or $F_{2^{11}-1}$. The first nontrivial Mersenne prime $M_{l}$ such that $F_{2^{13}-1}$ represents $M_{l}$ is $M_{521}$. For the $F_{2^{13}-1}$-solution $(x, y)$ of $M_{521}$ we have $8 \mid x$.

Theorem (4.2) will explain the divisibility of $x$ by 8 for all these examples.

## Chapter 2

## Some class field theory

In this chapter we will state the theorems we use in chapter three and four. We will define Hilbert class field, the Artin map, ray class field and ring class field. When we have done this, we can build up the conditions, as in [Cox], for deciding whether a prime is of the form $x^{2}+d \cdot y^{2}$ or not.

We will refer a lot to the book of Cox (see [Cox]), therefore we will use his less usual definition of a number field. We define a number field $K$ to be a subfield of the complex numbers $\mathbb{C}$ which has finite degree over the rational numbers $\mathbb{Q}$. Let $K$ and $L$ be number fields. The ring of algebraic integers of $K$ will be denoted by $\mathbb{Z}_{K}$. The disciminant of $L / K$ will be denoted by $\Delta(L / K)$. The discrimant of a polynomial $f$ will be denoted by $\Delta(f)$. Let $\alpha$ be an element of $L$. The minimal polynomial of $\alpha$ over $K$ will be denoted by $f_{K}^{\alpha}$. We denote the norm map from the fractional ideals of $L$ to the fractional ideals of $K$ by $\mathbf{N}_{L / K}$.

## Ramification and discriminant

If you want to use class field theory, like we do, it is important to know which primes ramify. Therefore we will state some useful theorems about ramification.

Theorem 2.1 Let $L / K$ be an extension of number fields. Then a prime $\pi$ of $K$ ramifies in the extension $\mathbb{Z}_{K} \subset \mathbb{Z}_{L}$ if and only if it divides $\Delta(L / K)$.

Proof: See [FT] page 126 .
Theorem 2.2 Let $L / K$ be an extension of number fields. Suppose $L=K(\alpha)$ for an element $\alpha \in \mathbb{Z}_{L}$ then $\Delta(L / K) \mid \Delta\left(f_{K}^{\alpha}\right) \cdot \mathbb{Z}_{K}$.

Proof: See [FT] page 121 .
Theorem 2.3 Given a tower of number fields $K \subset L \subset M$, we have the identity

$$
\Delta(M / K)=\boldsymbol{N}_{L / K}(\Delta(M / L)) \cdot \Delta(L / K)^{[M: L]}
$$

Proof: See [FT] page 126 .

Theorem 2.4 Let $L$ and $M$ be linearly disjoint extensions of a number field $K$, and suppose that $\Delta(L / K)$ and $\Delta(M / K)$ are coprime in $\mathbb{Z}_{K}$. Then we have $\mathbb{Z}_{L M}=\mathbb{Z}_{L} \cdot \mathbb{Z}_{M}$ and $\Delta(L M / K)=\Delta(L / K)^{[M: K]} \cdot \Delta(M / K)^{[L: K]}$.

Proof: See [Lang] page 68.

## Infinite primes

Finite primes of a number field $K$ are just the maximal ideals of $\mathbb{Z}_{K}$, the ring of algebraic integers of $K$. The infinite primes are determined by the embedding of a number field into the complex numbers $\mathbb{C}$. We have two kind of infinite primes. A real infinite prime is an embedding $\sigma: K \rightarrow \mathbb{R}$ and a complex infinite prime is an unordered pair of complex conjugated embeddings $\sigma, \bar{\sigma}: K \rightarrow \mathbb{C}$ with $\sigma \neq \bar{\sigma}$. So $\mathbb{Q}$ has one prime at infinity and $K=\mathbb{Q}(\sqrt[3]{2})$ has two primes at infinity.

Let $K \subset L$ be number fields and $\varphi, \tau$ infinite primes in $K, L$ respectively. We say $\tau$ lies above $\varphi$ if and only if $\left.\tau\right|_{K}=\varphi$. If this is the case, we will write $\tau \mid \varphi$. Each infinite prime $\varphi$ of $K$ gives rise to an absolute value on $K$. Indeed, let $\alpha \in K$ and let $|\cdot|$ the Euclidean distance function on $\mathbb{C}$. If $\varphi$ is a real infinite prime, say $\varphi$ is the imbedding $\sigma: K \rightarrow \mathbb{C}$, then we define $|\alpha|_{\varphi}$ to be $|\sigma(\alpha)|$. If $\varphi$ is a complex infinite prime, say $\varphi$ is the pair of complex conjugated embeddings $\sigma, \bar{\sigma}: K \rightarrow \mathbb{C}$, then we define $|\alpha|_{\varphi}$ to be $|\sigma(\alpha)|$. This is well defined since $|\sigma(\alpha)|=|\bar{\sigma}(\alpha)|$. Let $\varphi$ be an infinite prime then we have the following absolute value on $K$

$$
\alpha \mapsto|\alpha|_{\varphi} .
$$

By $K_{\varphi}$ we will mean the completion of $K$ induced by the absolute value $|\cdot|_{\varphi}$. The field $K_{\varphi}$ will be $\mathbb{R}$, whenever $\varphi$ is a real infinite prime, or $\mathbb{C}$, whenever $\varphi$ is a complex infinite prime. Now suppose that $\tau \mid \varphi$ and $K_{\varphi} \neq L_{\tau}$ then we say that $\varphi$ ramifies in $L$.

Theorem 2.5 Let $K \subset L$ be number fields. Let $\varphi$ be an infinite prime of $K$ and let $\tau$ be an infinite prime of $L$ above $\varphi$. Then

$$
\sum_{\tau \mid \varphi}\left[L_{\tau}: K_{\varphi}\right]=[L: K] .
$$

Proof: See [Lang] page 39.
We give an example of theorem (2.5). Let $\infty$ be the infinite prime of $\mathbb{Q}$. Let $\tau$ be an infinite prime of $K=\mathbb{Q}(\sqrt[3]{2})$. Clearly $\tau$ lies above $\infty$. So we have using theorem (2.5)

$$
\sum_{\tau \mid \infty}\left[K_{\tau}: \mathbb{Q}_{\infty}\right]=[\mathbb{R}: \mathbb{R}]+[\mathbb{C}: \mathbb{R}]=1+2=[K: \mathbb{Q}]
$$

Now we can talk about unramified extensions.

### 2.1 Hilbert class field

We say that a number field $L$ is unramified over a number field $K \subset L$ if every prime, finite or infinite, of $K$ is unramified in $L$. We define $\bar{K}$ to be the algebraic closure of the number field $K$ in $\mathbb{C}$.

Theorem 2.6 For every number field $K$ there exist a finite abelian unramified extension $H(K)$ in $\bar{K}$, such that if $L$ is an unramified abelian extension of $K$ in $\bar{K}$, then we have $L \subset H(K)$. Furthermore, we have $\mathrm{Cl}(K) \simeq \operatorname{Gal}(H(K) / K)$, where $\mathrm{Cl}(K)$ is the class group of $K$ and $\operatorname{Gal}(H(K) / K)$ is the Galois group of $H(K)$ over $K$.

Proof: See [Cox] page 106 and 109.
The field $H(K)$ is called the Hilbert class field of $K$. It is the maximal unramified abelian extension of $K$ in $\bar{K}$. A theorem of Minkowski, see [Cohen] page 195 , says that for every number field $K$ different from $\mathbb{Q}$ we have $|\Delta(K / \mathbb{Q})|$, the absolute value of the discriminant of $K$ over $\mathbb{Q}$, is bigger then 1 . From theorem $(2.6)$ we get that $\operatorname{Cl}(\mathbb{Q}) \simeq \operatorname{Gal}(\mathbb{Q} / \mathbb{Q}) \simeq\{i d\}$, so the class number of $\mathbb{Q}$ is 1 , and we rediscover the well known fact that $\mathbb{Z}$ is a unique factorization domain.

### 2.2 The Artin map

Theorem (2.6) says that there is an isomorphism between the class group $\mathrm{Cl}(K)$ and the Galois group $\operatorname{Gal}(H(K) / K)$. In this section we will give a canonical map. We will follow mainly [Lang].

Let $L / K$ be a Galois extension of number fields with $G=\operatorname{Gal}(L / K)$. Let $\pi$ be a finite prime of $K$ and let $\rho_{1}$ and $\rho_{2}$ be primes of $L$ above $\pi$. We know that there exist $\sigma \in G$ such that $\rho_{1}=\sigma\left(\rho_{2}\right)$ (see [Lang] page 12). And if $\sigma \in G$ then $\sigma\left(\rho_{1}\right)$ lies above $\pi$. Let $\rho$ be a prime above $\pi$ in $L$. Let $G_{\rho}=\{\sigma \in G \mid \sigma(\rho)=\rho\}$ be the decomposition group of the prime $\rho$ of $L$. We have $G_{\rho_{1}}=\sigma G_{\rho_{2}} \sigma^{-1}$ if $\rho_{1}=\sigma\left(\rho_{2}\right)$. So if the Galois group $G$ is abelian, then we have $G_{\rho_{1}}=G_{\rho_{2}}$. Since every element $\sigma$ of $G_{\rho}$ leaves $\rho$ fixed and is the identity on $\mathbb{Z}_{K} / \pi$, the element $\sigma$ induces an element $\bar{\sigma}$ of the Galois group of $\mathbb{Z}_{L} / \rho$ over $\mathbb{Z}_{K} / \pi$. This gives us a surjective group homomorphism (see [Lang] page 16)

$$
G_{\rho} \rightarrow \operatorname{Gal}\left(\left(\mathbb{Z}_{L} / \rho\right) /\left(\mathbb{Z}_{K} / \pi\right)\right),
$$

given by

$$
\sigma \longmapsto \bar{\sigma} .
$$

The kernel of the homomorphism is called the inertia group and it is denoted by $I_{\rho}$. The fixed field of the decomposition group of a prime $\rho$ is called the decomposition field of $\rho$. The fixed field of the inertia group of $\rho$ is called the inertia field of $\rho$. These two fields have very nice properties. The decomposition
field $D$ of $\rho$ is the smallest subfield of $L$ containing $K$ such that $\rho$ is the only prime of $L$ lying above the prime $\rho \cap D$ of $D$. The ramification index $e(\rho \cap D / \pi)$ and the residue index $f(\rho \cap D / \pi)$ are both equal to 1 . The inertia field $I$ of $\rho$ is the smallest subfield of $L$ containing $K$ such that the prime $\rho \cap I$ is totally ramified in $L$. The ramification index $e(\rho / \pi)$ equals $[L: I]$ and the residue class degree $f(\rho / \pi)$ equals $[I: D]$.

For the rest of this section we assume that $\pi$ is a finite prime of $K$ unramified in $L$. By the theory of finite fields there exists a unique element $\bar{\sigma}$ of $\operatorname{Gal}\left(\left(\mathbb{Z}_{L} / \rho\right) /\left(\mathbb{Z}_{K} / \pi\right)\right)$, called the Frobenius automorphism, that has the effect

$$
\bar{\sigma}(x) \equiv x^{\mathrm{N}(\pi)} \bmod \rho \quad \forall x \in \mathbb{Z}_{L}
$$

So every unramified prime $\rho$ above $\pi$ of $L$ gives us a unique element $\bar{\sigma}$ of $\operatorname{Gal}\left(\left(\mathbb{Z}_{L} / \rho\right) /\left(\mathbb{Z}_{K} / \pi\right)\right)$. And since $\pi$ is unramified in $L$, we have $I_{\rho}=\{e\}$, so the map from $G_{\rho}$ to $\operatorname{Gal}\left(\left(\mathbb{Z}_{L} / \rho\right) /\left(\mathbb{Z}_{K} / \pi\right)\right)$ is an isomorphism. Hence we get a unique element $\sigma$ of $G_{\rho} \subset \operatorname{Gal}(L / K)$. We denote this unique element $\sigma$ by $\left(\frac{\rho}{L / K}\right)$.

For the rest of this section we assume that $K \subset L$ is an abelian extension of number fields. Since $L / K$ is abelian and $\left(\frac{g(\rho)}{L / K}\right)=g\left(\frac{\rho}{L / K}\right) g^{-1}$ for all $g \in G$ (see [Cox] page 107), we see that $\left(\frac{p}{L / K}\right)$ only depends on $\pi$. Hence every unramified prime $\pi$ of $K$ induces an element of the Galois group of $L / K$. We denote this element by $\left(\frac{\pi}{L / K}\right)$. Now we have a map from the prime ideals of $K$, which do not ramify in $L$, to $\operatorname{Gal}(L / K)$, given by

$$
\pi \longmapsto\left(\frac{\pi}{L / K}\right)
$$

We define the decomposition group of $\pi$, denoted by $G_{\pi}$, to be the decomposition group of a prime $\rho$ in $L$ above $\pi$. This is well defined since $L / K$ is abelian. We define the Frobenius of $\pi$ to be the unique element of $G_{\pi}$ that induces the Frobenius automorphism of $\operatorname{Gal}\left(\left(\mathbb{Z}_{L} / \rho\right) /\left(\mathbb{Z}_{K} / \pi\right)\right)$.
Now in words the map above says: Every prime ideal $\pi$ of $K$ is send to the Frobenius of $\pi$.

We can extend our map by multiplicativity. Let $I_{K}(\Delta(L / K))$ be the group of fractional ideals of $\mathbb{Z}_{K}$ prime to $\Delta(L / K)$, so every prime ideal in $I_{K}(\Delta(L / K))$ is unramified in $L$. If $i \in I_{K}(\Delta(L / K))$ and $i=\prod \pi^{e \pi}$, then we define

$$
\left(\frac{i}{L / K}\right)=\prod\left(\frac{\pi}{L / K}\right)^{e_{\pi}}
$$

Now we have a map,

$$
\begin{equation*}
I_{K}(\Delta(L / K)) \rightarrow \operatorname{Gal}(L / K) \tag{2.1}
\end{equation*}
$$

the Artin map, which is actually a surjective homomorphism (see [Lang] page 199).

We are interested in the kernel of the Artin map. First we define a couple of important terms.

Definition 2.7 Let $K$ be a number field. A modules $m$ of $K$ is a formal product $m_{0} \cdot m_{\infty}$ of finitely many finite primes $m_{0}$ and finitely many infinite real primes $m_{\infty}$, with the real primes all different from each other.

By $I_{K}(m)$ we will mean the group of all fractional ideals of $K$ relative prime to $m_{0}$.

Definition 2.8 Let $K$ be a number field and $m$ a modulus of $K$. We define $P_{K, 1}(m)$ to be the subgroup of $I_{K}(m)$ generated by the principal ideals $\alpha \cdot \mathbb{Z}_{K}$, with $\alpha \in \mathbb{Z}_{K}$, satisfying $\alpha \equiv 1 \bmod m_{0}$ and $\sigma(\alpha)>0$ for all infinite primes $\sigma$ of $K$ dividing $m_{\infty}$. We define $\mathrm{Cl}_{m}(K)$ to be the group $I_{K}(m) / P_{K, 1}(m)$.

Let $m$ be a modulus, such that every finite prime which ramifies in $L$, divides $m$. Then we have the Artin map

$$
\begin{equation*}
I_{K}(m) \rightarrow \operatorname{Gal}(L / K) \tag{2.2}
\end{equation*}
$$

It is not in general true that the kernel of this map contains $P_{K, 1}(m)$. But if we make a good choice for the modulus, this will be true. There is a "smallest" choice.

Theorem 2.9 Let $L / K$ be an abelian extension of number fields. Then there is a modulus $f=f(L / K)$ such that:
(i) A prime of $K$, finite or infinite, ramifies in $L$ if and only if it divides $f$.
(ii) Let $m$ be a modulus divisible by all primes which ramify in $L$. Then the kernel of the Artin map $I_{K}(m) \rightarrow \operatorname{Gal}(L / K)$ contains $P_{K, 1}(m)$ if and only if $f \mid m$.

Proof: See [Cox] page 162.
The $f(L / K)$ in theorem (2.9) is called the conductor of $L / K$. The following theorem gives us a good modulus.

Theorem 2.10 Let $K \subset L$ be an abelian extension of number fields. Let $\Delta(L / K)$ be the relative discriminant of $L$ over $K$. Let $m_{\infty}$ be the formal product of all real infinite primes of $K$ which ramify in $L$. Set $m=\Delta(L / K) \cdot m_{\infty}$. Then the Artin map induces a surjective group homomorphism

$$
\begin{equation*}
C l_{m}(K) \rightarrow \operatorname{Gal}(L / K) . \tag{2.3}
\end{equation*}
$$

Proof: The conductor $f(L / K)$ divides $\Delta(L / K) \cdot m_{\infty}$ (see [Cohen2] page 158). So by theorem (2.9) the theorem follows.

### 2.3 Ray class field and ring class field

In the previous section we started with an extension of number fields $L / K$. Now we will go the other way around and start with a number field $K$ and a modulus $m$ of $K$.

Fix $m$, then we can search for abelian extensions $L$ of $K$ in $\bar{K}$, the algebraic closure of $K$ in $\mathbb{C}$, with the following two properties:
1: Every prime of $K$, finite or infinite, which ramifies in $L$ divides $m$.
2: $P_{K, 1}(m)$ is contained in the kernel of the Artin map.
Let $\Omega_{m}(K)$ be the set of all abelian field extensions $L$ of $K$ which satisfy these two properties. Let $\Upsilon_{m}(K)$ be the set of all subgroups of $I_{K}(m)$ which contain $P_{K, 1}(m)$. There is a canonical bijection $\beth$ between $\Omega_{m}(K)$ and $\Upsilon_{m}(K)$ induced by the Artin map. Indeed, given a field $L \in \Omega_{m}(K)$ then the kernel of the Artin map $I_{K}(m) \rightarrow \operatorname{Gal}(L / K)$ is a group $H \in \Upsilon_{m}(K)$. And given a group $H \in \Upsilon_{m}(K)$ then the is a unique field $L \in \Omega_{m}(K)$ such that the kernel of the Artin map $I_{K}(m) \rightarrow \operatorname{Gal}(L / K)$ is $H$ (see [Cox] page 162). The bijection $\beth$ has the following nice property. Let $L_{1}, L_{2} \in \Omega_{m}(K)$ then $L_{1} \subset L_{2}$ if and only if $\beth\left(L_{1}\right) \supset \beth\left(L_{2}\right)$. Hence we have the following theorem.

Theorem 2.11 There is a field $R_{m}(K) \in \Omega_{m}(K)$ such that for every $L \in$ $\Omega_{m}(K)$, we have $L \subset R_{m}(K)$. Furthermore, the Artin map induces a group isomorphism

$$
\mathrm{Cl}_{m}(K) \rightarrow \operatorname{Gal}\left(R_{m}(K) / K\right)
$$

Proof: Take $R_{m}(K)=\beth\left(P_{K, 1}(m)\right)$.
The field $R_{m}(K)$ is called the ray class field of $K$ with modulus $m$. It is the maximal abelian extension of $K$ in $\bar{K}$ with the property, that only primes of $K$, which divide the modulus $m$, ramify in $R_{m}(K)$ and every prime ideal of $K$ in $P_{K, 1}(m)$ is completely split in $R_{m}(K)$. The group $\mathrm{Cl}_{m}(K)$ is called the ray class group of $K$ with modulus $m$. A basic result is that the number of elements of $\mathrm{Cl}_{m}(K)$ is finite (see [Cox] page 160), hence $R_{m}(K)$ is a finite extension of $K$. If we take $m=1$, then $R_{m}(K)=H(K)$ and $\mathrm{Cl}_{m}(K)=\mathrm{Cl}(K)$, so we see that the ray class field is a generalization of the Hilbert class field.

The most important field of chapter three will be the ring class field. Let $K$ be a quadratic number field and let $O$ be an order of $K$. Set $m=\left[\mathbb{Z}_{K}: O\right]$. We define $P_{K, \mathbb{Z}}(m)$ to be the subgroup of $I_{K}(m)$ generated by the principal ideals $\alpha \cdot \mathbb{Z}_{K}$, with $\alpha \in \mathbb{Z}_{K}$, satisfying $\alpha \equiv a \bmod m$ for a number $a$ with $\operatorname{gcd}(a, m)=1$. The field $\beth\left(P_{K, \mathbb{Z}}(m)\right)$ is called the ring class field of the order $O$ and we will denoted it by $\operatorname{Ri}(O)$. Clearly the Artin map induces an isomorphism between $I_{K}(m) / P_{K, \mathbb{Z}}(m)$ and $\operatorname{Gal}(\operatorname{Ri}(O) / K)$.

We have $m=\left[\mathbb{Z}_{K}: O\right]=1,2,3,4,6$ if and only if $P_{K, 1}(m)=P_{K, \mathbb{Z}}(m)$. And we have $P_{K, 1}(m)=P_{K, \mathbb{Z}}(m)$ if and only if $R_{m}(K)=\operatorname{Ri}(O)$. In chapter three we only need to calculate the ring class fields of orders $O$ with $\left[\mathbb{Z}_{K}: O\right]=1,2,6$. Hence we only need to calculate the ray class fields $R_{m}(K)$.

### 2.4 Calculating the ray class fields

In this section we will concentrate on calculating ray class fields of imaginary quadratic fields $K$. Our fields will be imaginary quadratic, therefore we may assume that our modulus $m=m_{0}$. We will give one way that might lead to the ray class field $R_{m}(K)$.

Let $K$ be a number field and $m$ a modulus. We want to find $R_{m}(K)$, the ray class field of $K$ with modulus $m$. From theorem (2.11) we know that $\mathrm{Cl}_{m}(K)$ is isomorphic to $G=\operatorname{Gal}\left(R_{m}(K) / K\right)$. So if we know the number of elements of $\mathrm{Cl}_{m}(K)$ then we know [ $\left.R_{m}(K): K\right]$. We have the following exact sequence

$$
0 \rightarrow \mathbb{Z}_{K}^{*} \rightarrow\left(\mathbb{Z}_{K} / m\right)^{*} \rightarrow \mathrm{Cl}_{m}(K) \rightarrow I_{K}(m) / P_{K}(m) \rightarrow 0
$$

Hence we have

$$
\# \mathrm{Cl}_{m}(K)=\#\left(I_{K}(m) / P_{K}(m)\right) \cdot \# i m\left(\left(\mathbb{Z}_{K} / m\right)^{*}\right)
$$

where $\operatorname{im}\left(\left(\mathbb{Z}_{K} / m\right)^{*}\right)$ is the image of the homomorphism $\mathbb{Z}_{K}^{*} \rightarrow\left(\mathbb{Z}_{K} / m\right)^{*}$.
Theorem 2.12 Let $K$ be a number fields and $m$ a modulus of $K$ then

$$
\# \mathrm{Cl}_{K}=\# I_{K}(m) / P_{K}(m) .
$$

Proof: See [Janusz] page 112 and 113.
Now $\# \mathrm{Cl}_{K}$ is the class number $h_{K}$ of $K$ which can be calculated with methods explained in [Stewart] chapter 10 or looked up in a table (for example [Koch] page 246). We also get from the exact sequence above

$$
\# i m\left(\left(\mathbb{Z}_{K} / m\right)^{*}\right)=\#\left(\mathbb{Z}_{K} / m\right)^{*} / \# i m\left(\mathbb{Z}_{K}^{*}\right)
$$

where $\operatorname{im}\left(\mathbb{Z}_{K}^{*}\right)$ is the image of the homomorphism $\mathbb{Z}_{K}^{*} \rightarrow\left(\mathbb{Z}_{K} / m\right)^{*}$. Using the Chinese remainder theorem and the fact that

$$
\#\left(\mathbb{Z}_{K} / \pi^{e_{\pi}}\right)^{*}=(\mathbf{N}(\pi)-1) \cdot(\mathbf{N}(\pi))^{\left(e_{\pi}-1\right)}
$$

(see [Cohen2] page 189) we see that the number of elements of $\left(\mathbb{Z}_{K} / m\right)^{*}$ is $\prod_{\pi_{i}}\left(\mathbf{N}\left(\pi_{i}\right)-1\right) \cdot\left(\mathbf{N}\left(\pi_{i}\right)\right)^{\left(e_{\pi_{i}}-1\right)}$, with $m=\pi_{1}^{e_{\pi_{1}}} \cdots \pi_{n}^{e_{\pi_{n}}}$ the prime decomposition of $m$. Combining what we have done so far we get:

$$
\begin{equation*}
\# \mathrm{Cl}_{m}(K)=\left\{h_{K} \cdot \prod_{\pi_{i} \mid m}\left(\mathbf{N}\left(\pi_{i}\right)-1\right) \cdot\left(\mathbf{N}\left(\pi_{i}\right)\right)^{\left(e_{\pi_{i}}-1\right)}\right\} / \#\left(i m\left(\mathbb{Z}_{K}^{*}\right)\right) \tag{2.4}
\end{equation*}
$$

Theorem 2.13 Let $K$ be a number field and $R=R_{m}(K)$ the ray class field of $K$ with modulus $m$. Let $L$ be an abelian extension of $K$ with conductor $f=f(L / K)$. If $f \mid m$ then

$$
L \subset R
$$

Proof: See [Cox] page 163.
For the fields $L$ of theorem (2.13) we know that only primes of $K$ dividing $m$ may ramify in $L$. So if we find a field $L$ which is abelian over $K$ and the only primes which ramify are primes dividing $m$, then we only need to check that $f(L / K) \mid m$. This leads us to calculating the conductor. But first we remark that the Hilbert class field of $K$ is contained in $R_{m}(K)$. Indeed $f(H(K) / K)=1$. Genus theory gives us a part of the Hilbert class field of an imaginary quadratic field.

Theorem 2.14 Let $K$ be an imaginary quadratic field with discriminant $d_{K}$. Let $p_{1}, \ldots, p_{r}$ be the odd primes dividing $d_{K}$. Set $p_{i}^{*}=(-1)^{\left(p_{i}-1\right) / 2} \cdot p_{i}$. Then

$$
K\left(\sqrt{p_{1}^{*}}, \ldots, \sqrt{p_{r}^{*}}\right) \subset H(K)
$$

with $H(K)$ the Hilbert class field of $K$.
Proof: See [Cox] page 121.
The field $K\left(\sqrt{p_{1}^{*}}, \ldots, \sqrt{p_{r}^{*}}\right)$ is called the genus field of $K$.
Let's go back to the conductor. Another very useful theorem is the following.
Theorem 2.15 Let $L / K$ be an abelian extension of number fields. Suppose that the prime $\pi$ of $K$ is tamely ramified in $L$ then

$$
\pi \| f(L / K)
$$

Furthermore, if $\pi$ is a prime of $K$ which is unramified in $L$ then

$$
\pi \nmid f(L / K)
$$

Proof: See [Cohen2] page 149 and [Janusz] page 188 and 189.
Theorem (2.15) does not tell us what to do if $\pi$ is wildly ramified. There will be one case in chapter three, namely the case $d=27$, where we have to deal with a wildly ramified prime. Fortunately, we find in [Janusz] chapter VI a general method to calculate the conductor. We can use this method in particular in the case where $\pi$ is wildly ramified. The theorem below is the main key and it uses local fields. We will define local fields first. Let $\pi$ be a finite prime of the number field $K$. We denote by $K_{\pi}$ the completion of $K$ with respect to the absolute value $|\cdot|_{\pi}$ (see [Lang] page 36 for more detail). The field $K_{\pi}$ is called a local field.

Theorem 2.16 Let $L / K$ be an abelian extension of number fields. Let $\pi$ be a prime of $K$ which ramifies in $L$ then

$$
\pi^{b} \| f(L / K)
$$

where $b$ is the smallest integer such that $1+\pi^{b} \mathbb{Z}_{K_{\pi}} \subseteq N_{\pi}\left(L_{\beta}^{*}\right)$, with $\beta$ a prime of $L$ above $\pi$ and $\mathbb{Z}_{K_{\pi}}$ the closure of $\mathbb{Z}_{K}$ in $K_{\pi}$.

Proof: See [Janusz] page 188 and 189.
With the theory above we can handle our examples.

## Chapter 3

## Criteria for solvability

In this chapter we will give a criterion to decide whether or not $F_{d}$ represents $p$. When we have done this we will look at the special cases where $p$ is a Mersenne prime and $d$ lies between 0 and 48 . With the criteria we get for these special cases, we can explain the numbers $\# s_{20}(d)$, we got in the table of chapter one.

### 3.1 Primes of the form $x^{2}+d \cdot y^{2}$

In [Cox] we find a sufficient and necessary condition to know for a fixed $d \in \mathbb{Z}_{>0}$ when we can write a prime as $x^{2}+d \cdot y^{2}$ for certain $x, y \in \mathbb{Z}_{\geq 0}$. We will discuss the idea of how this can be done and state the theorems we use. The most easy case is the following.

Theorem 3.1 Let $d \equiv 1,2 \bmod 4$ be a positive squarefree integer. Let $p$ be an odd prime not dividing $d$. Suppose that the class number of $\mathbb{Q}(\sqrt{-d})$ equals 1 , then

$$
F_{d} \text { represents } p \Leftrightarrow\left(\frac{-d}{p}\right)=1
$$

Proof:
$" \Rightarrow "$ : Because $p \nmid d$ and $p=x^{2}+d \cdot y^{2}$, we get $-d \cdot y^{2} \equiv x^{2} \bmod p$ so $\left(\frac{-d}{p}\right)=1$. $" \Leftarrow ":$ If $\left(\frac{-d}{p}\right)=1$ and $p \neq 2$ then $p$ splits in $\mathbb{Q}(\sqrt{-d})$, say $p \mathbb{Z}_{K}=\pi \bar{\pi}$. Because $h(\mathbb{Q}(\sqrt{-d}))=1$, we know that $\pi$ and $\bar{\pi}$ are principal. And because $d \equiv 1,2 \bmod 4$ is a positive squarefree integer, we have $\mathbb{Z}_{\mathbb{Q}(\sqrt{-d)}}=\mathbb{Z}[\sqrt{-d}]$. So we have let's say $\pi=(x+y \cdot \sqrt{-d})$ and $\bar{\pi}=(x-y \cdot \sqrt{-d})$. Hence we have $p \mathbb{Z}_{K}=\pi \bar{\pi}=(x+y \cdot \sqrt{-d})(x-y \cdot \sqrt{-d})=\left(x^{2}+d \cdot y^{2}\right)$. From this we see that $p=x^{2}+d \cdot y^{2}$. This completes the proof.

From the proof of theorem (3.1) it is clear that we need to make sure that the prime ideals above $p$ in $K=\mathbb{Q}(\sqrt{-d})$ are generated by elements of the form $x \pm y \cdot \sqrt{-d}$ in order to be able to write $p$ as $x^{2}+d \cdot y^{2}$ for certain $x, y \in \mathbb{Z}_{\geq 0}$. In
theorem (3.1) this was done by two assumptions. From the assumption $h_{K}=1$ we get that every ideal is a principal ideal. Combining this with the assumption $d \equiv 1,2 \bmod 4$ is positive and squarefree, we get that every ideal is generated by an element in $\mathbb{Z}[\sqrt{-d}]$.

Note that in theorem (3.1) we can change $\left(\frac{-d}{p}\right)=1$ with $p$ splits completely in $\mathbb{Q}(\sqrt{-d})$. First we will make a generalization of theorem (3.1) by dropping the assumption $h(K)=1$. The Hilbert class field of $K$ will be used for this.

Theorem 3.2 Let $d \equiv 1,2 \bmod 4$ be a positive squarefree integer. Let $p$ be an odd prime not dividing d. Then we have
$F_{d}$ represents $p \Leftrightarrow p$ splits completely in $H(K)$,
where $H(K)$ is the Hilbert class field of $K=\mathbb{Q}(\sqrt{-d})$.
Proof:
$" \Rightarrow$ ": The prime $p$ does not ramify in $K$, because $p$ does not divide the discriminant of $K$ over $\mathbb{Q}$, which is $-d$ or $-4 d$. And since $p=x^{2}+d \cdot y^{2}$ we have $p \mathbb{Z}_{K}=\pi \bar{\pi}$ with let's say $(x+y \sqrt{-d})=\pi \neq \bar{\pi}=(x-y \sqrt{-d})$. Using theorem (2.6) we get $\left(\frac{\pi}{H(K) / K}\right)=\left(\frac{\bar{\pi}}{H(K) / K}\right)=1$, hence $\pi$ splits completely in $H(K)$ and $\bar{\pi}$ splits completely in $H(K)$. We conclude that $p$ splits completely in $H(K)$. $" \Leftarrow "$ : Since $p$ splits completely in $H(K)$ we have $p \mathbb{Z}_{K}=\pi \bar{\pi}$ with $\pi \neq \bar{\pi}$ and $\left(\frac{\pi}{H(K) / K}\right)=\left(\frac{\bar{\pi}}{H(K) / K}\right)=1$. Using theorem (2.6) we get $\pi$ and $\bar{\pi}$ are principal ideals. We have $\mathbb{Z}_{K}=\mathbb{Z}[\sqrt{-d}]$, since $d \equiv 1,2 \bmod 4$ and $d>0$ is squarefree. Therefore we have $x, y \in \mathbb{Z}$ with $p \mathbb{Z}_{K}=\pi \cdot \bar{\pi}=(x+y \cdot \sqrt{-d}) \cdot(x-y \cdot \sqrt{-d})=$ $\left(x^{2}+d \cdot y^{2}\right)$. From this we see that $p=x^{2}+d \cdot y^{2}$. This completes the proof.

In the theorem below we give a more elementary way of saying that $p$ splits completely in $H(K)$.

Theorem 3.3 Let $d \equiv 1,2 \bmod 4$ be a positive squarefree integer. Then there is a monic irreducible polynomial $f=f_{\mathbb{Q}}^{\alpha}(x)$ of degree $[H(K): K]$ in $\mathbb{Z}[x]$, with $K=\mathbb{Q}(\sqrt{-d})$ and $H(K)$ the Hilbert class field of $K$, such that if $p$ is an odd prime neither dividing $d$ nor $\Delta(f)$, then

$$
F_{d} \text { represents } p \Leftrightarrow\left(\frac{-d}{p}\right)=1 \text { and } f \equiv 0 \bmod p \text { has an integer solution } .
$$

Furthermore, $f$ may be taken to be the minimal polynomial of a real algebraic integer $\alpha$ for which $H(K)=K(\alpha)$.

## Proof:

We will work in the following fields $\mathbb{Q} \subset K \subset H(K)$ and $L=\mathbb{R} \cap H(K)$. Let $\tau$ be complex conjugation. Because $\tau(H(K))$ is unramified over $\tau(K)=K$ we see that $\tau(H(K)) \subset H(K)$, by theorem (2.6). Therefore $H(K)$ is Galois over $\mathbb{Q}$. The fixed field of the subgroup generated by $\tau$ is contained in $\mathbb{R}$, so this field is $L$ and $[H(K): L]=2$. Let $\alpha$ be an algebraic integer such that $L=\mathbb{Q}(\alpha)$ and let $f=f_{L / \mathbb{Q}}^{\alpha}$ be the minimal polynomial of $\alpha$ over $\mathbb{Q}$. Because the compositum of
$L$ and $K$ is $H(K)$, the polynomial $f$ can also be seen as the minimal polynomial of $H(K)$ over $K$.
$" \Rightarrow$ " Suppose that $p=x^{2}+d \cdot y^{2}$. Since $p$ is an odd prime not dividing $d$, we have using (3.2) that $p$ splits completely in $H(K)$ and $\left(\frac{-d}{p}\right)=1$. Thus $p$ splits completely in $L$. And with the Kummer-Dedekind theorem (see [Cohen] page 299) we see that $f \equiv 0 \bmod p$ has an integer solution.
$" \Leftarrow "$ : Suppose that $\left(\frac{-d}{p}\right)=1$ then $p$ splits in $K$, let's say $p \mathbb{Z}_{K}=\pi \bar{\pi}$. Because $\left(\mathbb{Z}_{K} / \pi\right) \cong \mathbb{F}_{p}$ we see $f \equiv 0 \bmod \pi$ has a solution. And because $H(K) / K$ is Galois and $p$ does not divide $\Delta(f)$, we see that $\pi$ splits completely in $H(K)$. With the same argument we get $\bar{\pi}$ splits completely in $H(K)$. We conclude that $p$ splits completely in $H(K)$. Hence using theorem (3.2) we get $F_{d}$ represents $p$. This completes the proof.

There are only finite $p$ 's excluded in theorem (3.3). For these $p$ 's one can use the algorithm of Cornacchia to check whether or not $p$ is represented by $F_{d}$. For all other $p$ 's one has to find the polynomial $f$ of theorem (3.3). In [Cox] we find a systematic method, which uses modular functions and complex multiplication, to calculate $f$.

Next we will drop the assumption $d \equiv 1,2 \bmod 4$ and $d$ squarefree. The problem will be that the principal ideals of $\mathbb{Q}(\sqrt{-d})$ do not have to be generated by an element of the form $x+y \cdot \sqrt{-d}$. We will use the ring class field of $\mathbb{Z}[\sqrt{-d}]$ for this problem.

Theorem 3.4 Let d be a positive integer. Let $p$ be an odd prime not dividing d. Then we have

$$
F_{d} \text { represents } p \Leftrightarrow p \text { splits completely in } \operatorname{Ri}(\mathbb{Z}[\sqrt{-d}]) \text {, }
$$

where $\operatorname{Ri}(\mathbb{Z}[\sqrt{-d}])$ is the ring class field of the order $\mathbb{Z}[\sqrt{-d}]$ of $\mathbb{Q}(\sqrt{-d})$.

## Proof:

Let $K=\mathbb{Q}(\sqrt{-d})$ and let $O=\mathbb{Z}[\sqrt{-d}]$. We have $\mathbb{Z}_{K}=\mathbb{Z}+m \mathbb{Z}_{K}$, where $m=\left[\mathbb{Z}_{K}: O\right]$ (see [Cox] page 133). We also have $\Delta(O)=-4 d=m^{2} \Delta(K / \mathbb{Q})$. $" \Rightarrow "$ : Since $\Delta(K / \mathbb{Q}(\sqrt{-d})) \mid 4 d$ we see that $p$, our odd prime not dividing $d$, does not ramify in $K$. And since $p=x^{2}+d \cdot y^{2}$ we have $p \mathbb{Z}_{K}=\pi \bar{\pi}$ with let's say $(x+y \sqrt{-d})=\pi \neq \bar{\pi}=(x-y \sqrt{-d})$. Because $p$ does not divide $m$ we see that $\pi, \bar{\pi} \in P_{K, \mathbb{Z}}(m)$. Hence we get $\left(\frac{\pi}{R i(O) / K}\right)=\left(\frac{\bar{\pi}}{R i(O) / K}\right)=1$. So $\pi$ splits completely in $\operatorname{Ri}(O)$ and $\bar{\pi}$ splits completely in $\operatorname{Ri}(O)$. We conclude that $p$ splits completely in $\operatorname{Ri}(O)$.
$" \Leftarrow "$ : Since $p$ splits completely in $\operatorname{Ri}(O)$ we have $p \mathbb{Z}_{K}=\pi \bar{\pi}$ with $\pi \neq \bar{\pi}$ and $\left(\frac{\pi}{\operatorname{Ri}(O) / K}\right)=\left(\frac{\bar{\pi}}{\operatorname{Ri}(O) / K}\right)=1$. Hence $\pi$ and $\bar{\pi}$ are elements of $P_{K, \mathbb{Z}}(m)$. Therefore we have $x, y \in \mathbb{Z}$ with $p \mathbb{Z}_{K}=\pi \cdot \bar{\pi}=(x+y \cdot \sqrt{-d}) \cdot(x-y \cdot \sqrt{-d})=\left(x^{2}+d \cdot y^{2}\right)$. From this we see that $p=x^{2}+d \cdot y^{2}$. This completes the proof.

We want to give a more elementary way of saying that $p$ splits completely in $\operatorname{Ri}(O)$ in case where $\operatorname{Ri}(O)$ equals $R_{m}(K)$.

Theorem 3.5 Let d be a positive integer. Let $R_{m}(K)$ be the ray class field of $K=\mathbb{Q}(\sqrt{-d})$ with modulus $m=\left[\mathbb{Z}_{K}: \mathbb{Z}[\sqrt{-d}]\right]$. Suppose that the integer $m \in$ $\{1,2,3,4,6\}$. Then there is a minimal monic irreducible polynomial $f=f_{\mathbb{Q}}^{\alpha}(x)$ of $R_{m}(K) \cap \mathbb{R}$ over $\mathbb{Q}$ in $\mathbb{Z}[x]$, such that if an odd prime $p$ divides neither $d$ nor the discriminant of $f$, then
$F_{d}$ represents $p \Leftrightarrow\left(\frac{-d}{p}\right)=1$ and $f \equiv 0 \bmod p$ has an integer solution.
Furthermore, $f$ may be taken to be the minimal polynomial of a real algebraic integer $\alpha$ for which $R_{m}(K)=K(\alpha)$.

## Proof:

Let $O=\mathbb{Z}[\sqrt{-d}]$. Since $\left[\mathbb{Z}_{K}: \mathbb{Z}[\sqrt{-d}]\right]=1,2,3,4,6$ we have $\operatorname{Ri}(O)=R_{K}(m)$. We will work in the following fields $\mathbb{Q} \subset K \subset R_{m}(K)$ and $L=\mathbb{R} \cap R_{m}(K)$. Let $\tau$ be complex conjugation. Because $\tau\left(R_{m}(K)\right)$ is an abelian extension of $K$ with conductor $\tau(m)=m$ we see that $\tau\left(R_{m}(K)\right) \subset R_{m}(K)$, by theorem (2.11). Therefore $R_{m}(K)$ is Galois over $\mathbb{Q}$. The fixed field of the subgroup generated by $\tau$ is contained in $\mathbb{R}$, so this field is $L$ and $\left[R_{m}(K): L\right]=2$. Let $\alpha$ be an algebraic integer such that $L=\mathbb{Q}(\alpha)$ and let $f=f_{L / \mathbb{Q}}^{\alpha}$ be the minimal polynomial of $\alpha$ over $\mathbb{Q}$. Because the compositum of $L$ and $K$ is $R_{m}(K)$, the polynomial $f$ can also be seen as the minimal polynomial of $R_{m}(K)$ over $K$.
$" \Rightarrow$ " Suppose that $p=x^{2}+d \cdot y^{2}$. Since $p$ is an odd prime not dividing $d$, we have using (3.4) that $p$ splits completely in $R_{m}(K)$ and $\left(\frac{-d}{p}\right)=1$. Thus $p$ splits completely in $L$. And with the Kummer-Dedekind theorem (see [Cohen] page 299) we see that $f \equiv 0 \bmod p$ has an integer solution.
$" \Leftarrow "$ : Suppose that $\left(\frac{-d}{p}\right)=1$ then $p$ splits in $K$, let's say $p \mathbb{Z}_{K}=\pi \bar{\pi}$. Because $\left(\mathbb{Z}_{K} / \pi\right) \cong \mathbb{F}_{p}$ we see $f \equiv 0 \bmod \pi$ has a solution. And because $R_{m}(K) / K$ is Galois and $p$ does not divide $\Delta(f)$, we see that $\pi$ splits completely in $R_{m}(K)$. With the same argument we get $\bar{\pi}$ splits completely in $R_{m}(K)$. We conclude that $p$ splits completely in $R_{m}(K)$. Hence using theorem (3.4) we get $F_{d}$ represents $p$. This completes the proof.

If you want to know how to find the polynomial $f$ in theorem (3.5) then you might want to read the text after the proof of theorem (3.3).

In chapter one we mentioned that for $d=3,7,15$ we have $\mid \# s_{20}(d)-$ $\# s_{20}(2 d) \mid \leq 1$. For the cases $d=3,15$ the following proposition will be used to prove that if $d \neq M_{l}$ then $F_{d}$ represents $M_{l}$ if and only if $F_{2 d}$ represents $M_{l}$.

Proposition 3.6 Let $d \equiv 3 \bmod 4$ be a positive squarefree integer. Suppose that $L=R_{2}(\mathbb{Q}(\sqrt{-d}))(\sqrt{2})=H(\mathbb{Q}(\sqrt{-2 d}))$. Let $M_{l}$ be a Mersenne prime unramified in $L$ then

$$
F_{d} \text { represents } M_{l} \Leftrightarrow F_{2 d} \text { represents } M_{l} .
$$

## Proof:

We have $M_{l}=\left(\sqrt{2}^{l}-1\right) \cdot\left(\sqrt{2}^{l}+1\right)$, so $M_{l}$ splits in $\mathbb{Q}(\sqrt{2})$. We want to use
theorem (3.4). The prime $M_{l}$ is unramified in $L$, so we have $M_{l} \nmid 2 d$. We have $\left[\mathbb{Z}_{\mathbb{Q}(\sqrt{-d})}: \mathbb{Z}[\sqrt{-d}]\right]=2$, because $d \equiv 3 \bmod 4$ is a positive squarefree integer. Using the fact that $M_{l}$ splits in $\mathbb{Q}(\sqrt{2})$ and theorem (3.4) we get: $F_{d}$ represents $M_{l}$ if and only if $M_{l}$ splits completely in $R_{2}(\mathbb{Q}(\sqrt{-d}))(\sqrt{2})$. We have $\left[\mathbb{Z}_{\mathbb{Q}(\sqrt{-2 d})}: \mathbb{Z}[\sqrt{-2 d}]\right]=1$, so with theorem (3.4) we get: $F_{2 d}$ represents $M_{l}$ if and only if $M_{l}$ splits completely in $H(\mathbb{Q}(\sqrt{-2 d})$. By assumption we have $R_{2}(\mathbb{Q}(\sqrt{-d}))(\sqrt{2})=H(\mathbb{Q}(\sqrt{-2 d}))$, so the theorem follows. This completes the proof.

The next proposition will be used in the proof of theorem (4.1) and in chapter three. In the proof of this proposition we will use the following theorem.

Theorem 3.7 Let $K$ be an imaginary quadratic field. Then an Abelian extension $L$ of $K$ is generalized dihedral over $\mathbb{Q}$, if and only if $L$ is contained in a ring class field of $K$.

Proof: See [Cox] page 191.
So if $L$ is contained in a ring class field of $K$ then we know that $L$ over $\mathbb{Q}$ is Galois. And the Galois group $\operatorname{Gal}(L / \mathbb{Q})$ is isomorphic to $\operatorname{Gal}(L / K) \rtimes(\mathbb{Z} / 2 \mathbb{Z})$, where the nontrivial element $\tau$ of $\mathbb{Z} / 2 \mathbb{Z}$ acts on $\operatorname{Gal}(L / K)$ via conjugation by $\tau$ and this action sends every element of $\operatorname{Gal}(L / K)$ to its inverse.

Proposition 3.8 Let $d \equiv 3 \bmod 4$ be a squarefree positive integer. Suppose that there exists a cyclic extension $H_{4}$ of $S=\mathbb{Q}(\sqrt{-2 \cdot d})$, with $\left[H_{4}: S\right]=4, H_{4} \subset$ $H(S)$ and $\sqrt{2} \in H_{4}$. Let $M_{l}$ be a Mersenne prime. Suppose that $l \equiv 1 \bmod 2 n$, where $n$ is equal to the order of 2 in the group $(\mathbb{Z} / d)^{*}$, then $M_{l}$ splits completely in $H_{4}$.

## Proof:

Let $K=\mathbb{Q}(\sqrt{-d})$ and let $J=\mathbb{Q}(\sqrt{2})$. Because $\sqrt{2}$ is an element of $H_{4}$, we have that $J$ is contained in $H_{4}$. From the final part of theorem (3.7) it follows that $\operatorname{Gal}\left(H_{4} / \mathbb{Q}\right)$ is isomorphic to the dihedral group with 8 elements. So there are two conjugated field extensions of $J$, say $J_{1}$ and $J_{2}$, contained in $H_{4}$. We have the following field diagram.

The discriminant of $J K$ over $J$ is $-d$. To see this use theorem (2.4) on the extensions $K$ and $J$ of $\mathbb{Q}$ and the fact that $d \equiv 3 \bmod 4$ to calculate the ring of algebraic integers $\mathbb{Z}_{J K}$. Then one sees that $\mathbb{Z}_{J K}$ is a free module over $\mathbb{Z}_{J}$, so one can easily calculate the discriminant $\Delta(J K / J)$. The discriminants $\Delta\left(J_{1} / J\right)$ and $\Delta\left(J_{2} / J\right)$ must be relative prime. To see this suppose that the discriminants were not relative prime. Then we would have a prime of $J$ which would be ramified in $J_{1}$ and $J_{2}$. This prime would also be ramified in $J K$, because $\Delta\left(H_{4} / J K\right)=1$. But then the inertia field of this prime equals $J$, which cannot be the case since $\Delta\left(H_{4} / J K\right)=1$. Using theorem (2.3) on the extension $J \subset$ $J K \subset H_{4}$ and theorem (2.4) on the linearly disjoint extension $J_{1}$ and $J_{2}$ of $J$ we get $-d=\Delta\left(J_{1} / J\right) \Delta\left(J_{2} / J\right)$. Now take $v_{l}=\frac{\sqrt{2}^{l}-1}{\sqrt{2}-1}$ and $\tilde{v}_{l}=\frac{\sqrt{2}^{l}+1}{\sqrt{2}+1}$ (note $\left.v_{l} \cdot \tilde{v}_{l}=M_{l}=2^{l}-1\right)$. Using the fact that $l$ is odd we see that $v_{l}$ and $\tilde{v}_{l}$ are both elements of $\mathbb{Z}_{J}$. Because $l \equiv 1 \bmod 2 n$ we have $\sqrt{2}^{l} \equiv \sqrt{2} \bmod (d) \mathbb{Z}_{J}$. Hence $v_{l} \equiv \tilde{v}_{l} \equiv 1 \bmod (d) \mathbb{Z}_{J}$ and also $\forall \sigma \in \operatorname{Gal}(J / \mathbb{Q})$ we have $\sigma\left(v_{l}\right)>0$ and $\sigma\left(\tilde{v}_{l}\right)>0$, because $l$ is odd implies $\sigma\left(\sqrt{2}^{l} \pm 1\right) \sigma(\sqrt{2} \pm 1)>0$. In other notation we have:

$$
v_{l} \equiv \tilde{v}_{l} \equiv 1 \bmod (d) \mathbb{Z}_{J} \quad \wedge \quad \forall \sigma \in \operatorname{Gal}(J / \mathbb{Q}) \text { we have } \sigma\left(v_{l}\right)>0 \text { and } \sigma\left(\tilde{v}_{l}\right)>0
$$

Using the Chinese remainder theorem, $\Delta\left(J_{1} / J\right)$ and $\Delta\left(J_{2} / J\right)$ are coprime, we get:

$$
\begin{gathered}
v_{l} \equiv \tilde{v}_{l} \equiv 1 \bmod \left(\Delta\left(J_{1} / J\right)\right) \mathbb{Z}_{J} \wedge v_{l} \equiv \tilde{v}_{l} \equiv 1 \bmod \left(\Delta\left(J_{2} / J\right)\right) \mathbb{Z}_{J} \wedge \\
\forall \sigma \in \operatorname{Gal}(J / \mathbb{Q}) \text { we have } \sigma\left(v_{l}\right)>0 \text { and } \sigma\left(\tilde{v}_{l}\right)>0
\end{gathered}
$$

Now we apply the Artin map and theorem 2.10. This gives:

$$
\left(\frac{\left(v_{i}\right)}{J_{i} / J}\right)=\left(\frac{\left(\tilde{v}_{l}\right)}{J_{i} / J}\right)=e \text { for } i \in\{1,2\}
$$

because $v_{l}$ and $\tilde{v}_{l}$ are in the kernel. The Galois group of $H_{4} / J$ is isomorphic to $\operatorname{Gal}\left(J_{1} / J\right) \times \operatorname{Gal}\left(J_{2} / J\right)$. So:

$$
\left(\frac{\left(v_{l}\right)}{H_{4} / J}\right)=\left(\frac{\left(\tilde{v}_{l}\right)}{H_{4} / J}\right)=e
$$

So $M_{l}$ splits completely in $H_{4}$. This completes the proof.
The following proposition will be used for the cases $d=14$ and $d=46$ in the next section.

Proposition 3.9 Let $p \equiv 3 \bmod 4$ be a prime. Suppose that $\mathrm{Cl}(\mathbb{Q}(\sqrt{-2 p}))$ is isomorphic to the cyclic group with four elements. Let $M_{l}$ be a Mersenne prime. Suppose that $l \equiv 1 \bmod 2 n$, where $n$ is equal to the order of 2 in the group $(\mathbb{Z} / p)^{*}$, then $F_{2 p}$ represents $M_{l}$.

## Proof:

From proposition (3.8) we know that $M_{l}$ splits completely in $H(\mathbb{Q}(\sqrt{-2 p}))$. Then we apply theorem (3.2). This completes the proof.

### 3.2 The cases with $d$ between 0 and 48.

In this section we will apply the theory of the previous section to decide whether or not $F_{d}$ represents $M_{l}$, where $M_{l}$ is a Mersenne prime and where $d$ lies between 0 and 48.

For the cases $d \equiv 0,1,2,4,5 \bmod 8$, with $d \neq 2$, we have $F_{d}$ doesn't represent $M_{l}$ (see proposition (1.1)). We will deal with the remaining cases below.

The case $d=2$.
From proposition (1.1) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{d}$ represents $M_{l}$ if and only if

$$
l=2
$$

The case $d=3$.
For $d=3$ we have $m=2$ (see theorem (3.5)). Because the class number of $K=\mathbb{Q}(\sqrt{-3})$ is 1 , we have that the ray class group of K is $\mathrm{Cl}_{2}(K)=$ $I_{K}(2) / P_{K, 1}(2)=P_{K}(2) / P_{K, 1}(2)$. Because $\frac{1+\sqrt{-3}}{2} \bmod 2 \mathbb{Z}_{K}$ is clearly in the kernel of the surjective group homomorphism $\left(\mathbb{Z}_{K} / 2\right)^{*} \rightarrow P_{K}(2) / P_{K, 1}(2)$, we see that the group $P_{K}(2) / P_{K, 1}(2)$ is trivial. So $R_{2}(K)=K$. Now $M_{l}=2^{l}-1$, so $M_{l} \equiv-1 \bmod 4$. If $l=2$ then we have the solution $3=0^{2}+3 \cdot 1^{2}$. Suppose $l \neq 2$ then $\left(\frac{-3}{M_{l}}\right)=\left(\frac{-1}{M_{l}}\right)\left(\frac{3}{M_{l}}\right)=(-1)\left(-\left(\frac{M_{l}}{3}\right)\right)=1$. With theorem (3.5) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{3}$ represents $M_{l}$.

The case $d=6$.
Suppose $d=6$. Then we have $K=\mathbb{Q}(\sqrt{-6})$. The class number of $K$ is 2 . So we get $[H(K): K]=2$. Using theorem (2.14) we have that $K(\sqrt{-3})=K(\sqrt{2})$ is unramified over $K$, so $H(K)=K(\sqrt{2})$. But now we have $R_{2}(\mathbb{Q} \sqrt{-3})(\sqrt{2})=$ $H(\mathbb{Q}(\sqrt{-6}))$. Using proposition (3.6) we get the following result: Suppose that $M_{l}$ is a Mersenne prime then $F_{6}$ represents $M_{l}$ if and only if

$$
l \neq 2
$$

The case $d=7$.
The next $d$ is $d=7$. The class number of $K=\mathbb{Q}(\sqrt{-7})$ is 1 and $m=2$. So $\mathrm{Cl}_{2}=P_{K}(2) / P_{K, 1}(2)$. Again we have the surjective homomorphism $\left(\mathbb{Z}_{K} / 2\right)^{*} \rightarrow$ $P_{K}(2) / P_{K, 1}(2)$. But 2 splits in $K$ so $\left(\mathbb{Z}_{K} / 2\right)^{*}$ has only one element. Therefore $R_{2}(K)=K$. Take $M_{l}=2^{l}-1$ with $l \neq 2,3$. Then $\left(\frac{-7}{M_{l}}\right)=\left(\frac{-1}{M_{l}}\right)\left(-\left(\frac{M_{l}}{7}\right)\right)=\left(\frac{M_{l}}{7}\right)$.
Now $\left(\frac{M_{l}}{7}\right)=1$ if and only if $l \equiv 1 \bmod 3$. With theorem (3.5) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{7}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 3 \text { or } l=3 .
$$

The case $d=11$.
Take $d=11$. Then $K=\mathbb{Q}(\sqrt{-11})$. The class number of $K$ is 1 and 2 is inert in $K$. So using (2.4) we get that $\left[R_{2}(K): K\right]=3$. From the discriminant $\Delta(K / \mathbb{Q})=-11$ and the modulus 2 we know that only the primes 2 and 11 of $\mathbb{Q}$ ramify in $R_{2}(K)$. Let's take a look at the field $L=R_{2}(K) \cap \mathbb{R}$ of degree 3 over $\mathbb{Q}$. We know that only 2 is totally ramified in $L$, because the modulus of $R_{2}(K)$ over $K$ is 2 and $R_{2}(K)$ over $K$ is Galois. From theorem (3.7) we get that the Galois group of $R_{2}(K)$ over $\mathbb{Q}$ is the $S_{3}$, therefore $R_{2}(K)$ is the Galois closure of $L$ over $\mathbb{Q}$. Suppose that 11 is unramified in $L$, then 11 would be unramified in all the conjugates of $L$ and therefore unramified in $R_{2}(K)$, which is not the case. From this we see that the different of $L / \mathbb{Q}$ only has the factors $\pi_{2}^{2}$ and $\pi_{11}$, with $\pi_{2}$ the prime above 2 and $\pi_{11}$ the ramified prime above 11 (see [Koch] page 33 for the theory about different and ramification). Because $K$ is contained in $R_{2}(K)$ and we know the factors of the different, we get $\Delta(L / \mathbb{Q})=-44$. In [Cohen] page 509 we find an irreducible polynomial of degree 3 with discriminant -44 , namely $f(x)=x^{3}-x^{2}-x-1$. Let $\alpha$ be a zero of $f(x)$. Then $S=\mathbb{Q}(\alpha)(\sqrt{-11})$ is the Galois closure of $\mathbb{Q}(\alpha)$ over $\mathbb{Q}$. Only the prime 2 of $K$ ramifies totally in $S$. The conductor of $S / K$ is therefore 2 , see theorem (2.15). So from theorem (2.13) we get $S=R_{2}(K)$. We have $\left(\frac{-11}{M_{l}}\right)=\left(\frac{M_{l}}{11}\right)$. Because $M_{l}=2^{l}-1$ is prime we have $l$ is prime so $l \equiv 1,3,7,9 \bmod 10$. This implies that $M_{l} \equiv 1,7,6,5 \bmod 11$ respectively. But only $1,5 \bmod 11$ are square. From theorem (3.5) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{11}$ represents $M_{l}$ if and only if

$$
l \equiv \pm 1 \bmod 5 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}-x^{2}-x-1 \equiv 0 \bmod M_{l}
$$

The case $d=14$.
The next $d$ is $d=14$. The class group of $K=\mathbb{Q}(\sqrt{-14})$ is cyclic of degree four. We want to use proposition (3.9). The order of 2 in $(\mathbb{Z} / 7)^{*}$ is three. From $\left(\frac{-14}{M_{l}}\right)=\left(\frac{2}{M_{i}}\right)\left(\frac{-7}{M_{l}}\right)=\left(\frac{-7}{M_{l}}\right)=1$ we get that $l \equiv 1 \bmod 3$ assuming that $F_{14}$ represents $M_{l}$ (see $d=7$ ). But since $l \neq 2$ is prime we have $l \equiv 1 \bmod 6$. So with proposition (3.9) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{14}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 3
$$

The case $d=15$.
Take $d=15$. Then the class number of $K=\mathbb{Q}(\sqrt{-15})$ is 2 and 2 splits in $K$. Using 2.4 we get $\left[I_{K}(2): P_{K, 1}(2)\right]=2$. Now we can use theorem (2.14) to see that $R_{2}(K)=K(\sqrt{5})$. From $\left(\frac{-15}{M_{i}}\right)=\left(\frac{M_{1}}{5}\right)$, we see that $l$ has to be equivalent to 1 modulo 4 assuming that $F_{15}$ represents $M_{l}$. And because the minimal polynomial of $R_{2}(K) / K$ is $x^{2}-5$ we see that this condition is enough to write $M_{l}$ as $x^{2}+15 \cdot y^{2}$. So with theorem (3.5) we get: Suppose that $M_{l}$ is a Mersenne
prime then $F_{15}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 4
$$

The case $d=19$.
Take $d=19$. This one looks just like $d=11$. Now $h_{K}=1$ and 2 is inert in $K=\mathbb{Q}(\sqrt{-19})$. So we have to find a irreducible polynomial $f(x)$ with discriminant $-4 \cdot 19$. In [Cohen] page 509 we find $f(x)=x^{3}-2 x-2$. From the other condition $\left(\frac{-19}{M_{l}}\right)=\left(\frac{-1}{M_{l}}\right)\left(-\left(\frac{M_{l}}{19}\right)\right)=\left(\frac{M_{l}}{19}\right)=1$, we get $l \equiv \pm 1 \bmod 18$ after some calculations. This gives: Suppose that $M_{l}$ is a Mersenne prime then $F_{19}$ represents $M_{l}$ if and only if

$$
l \equiv \pm 1 \bmod 9 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}-2 x-2 \equiv 0 \bmod M_{l}
$$

The case $d=22$.
Take $d=22$. The class number of $K=\mathbb{Q}(\sqrt{-22})$ is 2. By theorem (2.14) we have that $H(K)=K(\sqrt{-11})=K(\sqrt{2})$. Because $M_{l} \equiv-1 \bmod 8$ we have $\left(\frac{2}{M_{l}}\right)=1$, so the polynomial $x^{2}-2 \equiv 0 \bmod M_{l}$ has an integer solution. By theorem (3.3) we only need to check $\left(\frac{-22}{M_{i}}\right)=\left(\frac{-1}{M_{l}}\right)\left(\frac{2}{M_{l}}\right)\left(\frac{11}{M_{i}}\right)=(-1)(1)\left(-\left(\frac{M_{1}}{11}\right)\right)=$ $\left(\frac{M_{1}}{11}\right)$. Because $M_{l}=2^{l}-1$ is prime we have $l$ is prime so $l \equiv 1,3,7,9 \bmod 10$. This implies that $M_{l} \equiv 1,7,6,5 \bmod 11$ respectively. But only $1,5 \bmod 11$ are square. This gives use: Suppose that $M_{l}$ is a Mersenne prime then $F_{22}$ represents $M_{l}$ if and only if

$$
l \equiv \pm 1 \bmod 5 \text { or } l=5
$$

The case $d=23$.
Take $d=23$. Then $h_{K}=3$ and 2 splits in $K=\mathbb{Q}(\sqrt{-23})$. So $R_{2}(K)=H(K)$. We can use the same arguments of $d=11$. We have to find an irreducible polynomial of degree 3 with discriminant -23 . Now $f(x)=x^{3}+x^{2}-1$ is such a polynomial (see [Cohen] page 509). From $\left(\frac{-23}{M_{l}}\right)=\left(\frac{M_{l}}{23}\right)=1$ we get $l \equiv 1,2,5,7,8 \bmod 11$. This gives us: Suppose that $M_{l}$ is a Mersenne prime then $F_{23}$ represents $M_{l}$ if and only if

$$
l \equiv 1,2,5,7,8 \bmod 11 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}+x^{2}-1 \equiv 0 \bmod M_{l}
$$

The case $d=27$.
Take $d=27$. Then $m=6$ and $h_{K}=1$, with $K=\mathbb{Q}(\sqrt{-3})$. The units of $\mathbb{Z}_{K}$ are $\left\{ \pm 1, \pm \omega, \pm \omega^{2}\right\}$, with $\omega=\frac{-1+\sqrt{-3}}{2}$. Because we have an isomorphism from $\mathbb{Z}_{K}^{*}$ to $\left(\mathbb{Z}_{K} / 3 \mathbb{Z}_{K}\right)^{*}$ and the prime 2 of $\mathbb{Q}$ is inert in $K$, we get $\#\left(\mathrm{Cl}_{6}(K)\right)=3$ (see (2.4)). So we have to find an abelian extension $L$ of $K$ with conductor 6 and $[L: K]=3$. Take $L=K(\sqrt[3]{2})$, then clearly $L$ is an abelian extension of $K$ and $[L: K]=3$. Because the discriminant of $x^{3}-2$ is $-108=-2^{3} \cdot 3^{3}$
we have that only 2 and 3 ramify in $L$. Now we will calculate the conductor $f$ of $L$ over $K$. Using theorem (2.15) we get $2 \| f$. Now $\sqrt{-3}$ is not tamely ramified so we have to use theorem (2.16). The ring of algebraic integers of $L$ is $\mathbb{Z}_{L}=\mathbb{Z}\left[\frac{1+\sqrt{-3}}{2}, \sqrt[3]{2}\right]$. So the ring of integers of the local field $\mathbb{Q}_{3}(\sqrt{-3}, \sqrt[3]{2})$ is $B=\mathbb{Z}_{3}[\sqrt{-3}, \sqrt[3]{2}]$. Let $\beta=a+b \sqrt[3]{2}+c \sqrt[3]{2}^{2} \in B^{*}$ with $a, b, c \in A$ then $N(\beta)=a^{3}-2 b^{3}-6 a b c+4 c^{3} \in A^{*}$ with $A=\mathbb{Z}_{3}[\sqrt{-3}]$ the ring of integers of the local field $\mathbb{Q}_{3}(\sqrt{-3})$ and $N=\mathbf{N}_{\sqrt{-3}}$ the local norm. So we have $\left(A^{*}\right)^{3} \subset N\left(B^{*}\right)$. We will show that $\left(A^{*}\right)^{3}= \pm 1+\sqrt{-3}^{4} A$. Let $\alpha \in A^{*}$ then $\alpha= \pm 1+\sqrt{-3} n$ with $n \in A$. Now $\alpha^{3}=( \pm 1)+\left(n^{3}-n\right) \sqrt{-3}^{3}+( \pm 1) n^{2} \sqrt{-3}^{4}$, but $\sqrt{-3} \mid n^{3}-n$ because $n^{3} \equiv n \bmod \sqrt{-3}$. So $\left(A^{*}\right)^{3} \subset \pm 1+\sqrt{-3}^{4} A$. Let $x \in \pm 1+\sqrt{-3}^{5} A$. We will use Hensel's lemma (see [Lang] page 42) to show that $x \in\left(A^{*}\right)^{3}$. Therefore we have to prove that the polynomial $f(X)=X^{3} \mp x$ has a zero in $A$. But $|f(1)| \leq\left|\sqrt{-3}^{5}\right|<|3 \cdot 2|^{2}=\left|f^{\prime}(1)\right|^{2}$, so with Hensel's lemma we get $\pm 1+\sqrt{-3}^{5} A \subset\left(A^{*}\right)^{3} \subset \pm 1+\sqrt{-3}^{4} A$. But $2^{3}=-1+\sqrt{-3}^{4} \notin \pm 1+\sqrt{-3}^{5} A$ and $\left[ \pm 1+\sqrt{-3}^{4} A: \pm 1+\sqrt{-3}^{5} A\right]=3$, hence $\left(A^{*}\right)^{3}= \pm 1+\sqrt{-3}^{4} A \subset N\left(B^{*}\right)$. Let $(a, b, c)=a^{3}-2 b^{3}-6 a b c+4 c^{3}$. Take $(a, b, c)=( \pm 1, \pm \sqrt{-3}, 0)$ then we see that $\pm 1+\sqrt{-3}^{3}+\sqrt{-3}^{5}$ and $\pm 1-\sqrt{-3}^{3}-\sqrt{-3}^{5}$ are elements of $N\left(B^{*}\right)$, so $\pm 1 \pm \sqrt{-3}^{3} \in N\left(B^{*}\right)$, hence $\pm 1+\sqrt{-3}^{3} A \subset N\left(B^{*}\right)$. Taking $(0,0, \pm 1)$ and $(0, \pm 1,0)$ we see that $\pm 1 \pm \sqrt{-3}^{2} \in N\left(B^{*}\right)$, hence $\pm 1+\sqrt{-3}^{2} A \subset N\left(B^{*}\right)$. Because $\pm 1+\sqrt{-3} A=A^{*}$ and $\sqrt{-3}$ is ramified in $L$ we get $\pm 1+\sqrt{-3}^{2} A=$ $N\left(B^{*}\right)$ so $\left(\sqrt{-3}^{2}\right) \| f$, thus $f=6$. So $L=R_{6}(K)$. If $M_{l}>27$, which must be the case if $F_{27}$ represents $M_{l}$, then we have $\left(\frac{-3}{M_{l}}\right)=1$. For cyclic groups of order $n$ we know that there is a unique subgroup of order $d$ if $d \mid n$. Let $l \neq 2,3$. Then $3 \mid M_{l}-1$ so there exist a unique subgroup of index 3 in $\mathbb{F}_{M_{l}}^{*}$, namely $\left(\mathbb{F}_{M_{l}}^{*}\right)^{3}$. The order of the subgroup generated by 2 is $l$. Because $l \neq 3$ we have $3 \left\lvert\, \frac{p-1}{l}\right.$ so $2 \in\left(\mathbb{F}_{M_{l}}^{*}\right)^{3}$. Hence $x^{3}-2 \equiv 0 \bmod M_{l}$ always has a solution if $l \neq 2,3$. From theorem (3.5) we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{27}$ represents $M_{l}$ if and only if

$$
l \neq 2,3
$$

Now we are able to prove the following observation made in chapter one.
Theorem 3.10 Let $M_{l}>7$ be a Mersenne prime. Let $(x, y)$ be the $F_{3}$-solution of $M_{l}$ then $3 \mid y$.

## Proof:

If $M_{l}>7$ then $l>3$ so $F_{27}$ represents $M_{l}$, see case $d=27$. Let $\left(x^{\prime}, y^{\prime}\right)$ be the $F_{27}$-solution of $M_{l}$ then $\left(x^{\prime}, 3 y^{\prime}\right)$ is the $F_{3}$-solution of $M_{l}$. From proposition (0.3) we get that $\left(x^{\prime}, 3 y^{\prime}\right)=(x, y)$. Hence we have $3 \mid y$. This completes the proof.

The case $d=30$.
Take $d=30$. The class number of $K=\mathbb{Q}(\sqrt{-30})$ is 4 . With theorem (2.14) we get $H(K)$. But $H(K)=R_{2}(\mathbb{Q}(\sqrt{-15})(\sqrt{2})$ so from proposition (3.6) we get:

Suppose that $M_{l}$ is a Mersenne prime then $F_{30}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 4
$$

The case $d=31$.
Take $d=31$. Then $h_{K}=3$ and 2 is splits in $K=\mathbb{Q}(\sqrt{-31})$. The number of elements of $\mathrm{Cl}_{2}(K)$ is 3 . So $R_{2}(K)=H(K)$. So we have to find an irreducible polynomial of degree 3 . The polynomial $f(x)=x^{3}+x^{2}+1$ is such a polynomial. Hence we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{31}$ represents $M_{l}$ if and only if

$$
l \equiv 1,3 \bmod 5 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}+x^{2}+1 \equiv 0 \bmod M_{l} \text { or } l=5
$$

The case $d=35$.
Take $d=35$. Then $h_{K}=2$ and 2 is inert in $K=\mathbb{Q}(\sqrt{-35})$. The number of elements of $\mathrm{Cl}_{2}(K)$ is 6 . To find $R_{2}(K)$ we find two subfields of $R=R_{2}(K)$. First using theorem (2.14) we get $H(K)=K(\sqrt{5}) \subset R$. Using the same arguments as with $d=11$ we find the other field. Hence we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{35}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 12 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}+2 x-2 \equiv 0 \bmod M_{l}
$$

The case $d=38$.
Take $d=38$. Then $h_{K}=6$ with $K=\mathbb{Q}(\sqrt{-38})$. We have to find two unramified abelian extensions of $K$ of degree 2 and 3 . The first one $K(\sqrt{2})$ we find using theorem (2.14). The second one is an extension of $K$ of degree three. The polynomial $f(x)=x^{3}-x^{2}-2 x-2$ has discriminant $-152=-2^{3} \cdot 19$. Let $\alpha$ be a zero of $f$. The Galois closure of $\mathbb{Q}(\alpha)$ over $\mathbb{Q}$ is $L=K(\alpha)$ because it contains $\sqrt{-152}=4 \cdot \sqrt{-38}$. Only 2 and 19 ramify in $L$. We know from the discriminant of $f$ that 2 and 19 are not totally ramified in $\mathbb{Q}(\alpha)$, else $2^{2} \| \Delta(\mathbb{Q}(\alpha) / \mathbb{Q})$ and /or $19^{2} \| \Delta(\mathbb{Q}(\alpha) / \mathbb{Q})$. Because $L / K$ is Galois we have $e(\beta / \pi)=1,3$, with $\beta$ a prime in $L$ above a prime $\pi$ in $K$. Hence $L$ over $K$ is unramified. So $L$ is our field. From $d=19$ we know that $\left(\frac{-38}{M_{l}}\right)=1$ if and only if $l \equiv \pm 1 \bmod 9$. Hence we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{38}$ represents $M_{l}$ if and only if

$$
l \equiv \pm 1 \bmod 9 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}-x^{2}-2 x-2 \equiv 0 \bmod M_{l}
$$

The case $d=39$.
Take $d=39$. Then $\mathrm{Cl}(K)$ is the cyclic group with four elements and 2 splits in $K=\mathbb{Q}(\sqrt{-39})$. So $R_{2}(K)=H(K)$. By theorem (3.5) we know that $\operatorname{Gal}(H(K) / \mathbb{Q})$ is the dihedral group with eight elements. We will use the idea of proposition (3.8). So we have to find two irreducible polynomials in $\mathbb{Q}(\sqrt{13})[x]$ such that the product of there discriminants is -3 . Take $f_{1}(x)=$
$x^{2}+\left(1+\left(\frac{1+\sqrt{13}}{2}\right)\right) x+\left(1+\left(\frac{1+\sqrt{13}}{2}\right)\right)$ and $f_{2}(x)=x^{2}+\left(\frac{1+\sqrt{13}}{2}\right) x+1$. Then $\Delta\left(f_{1}\right) \Delta\left(f_{2}\right)=-\left(\frac{1+\sqrt{13}}{2}\right) \cdot-\left(\frac{1-\sqrt{13}}{2}\right)=-3$. From $\left(\frac{-39}{M_{i}}\right)=\left(\frac{M_{l}}{13}\right)=1$ we get $l \equiv 1 \bmod 3$. So if $l \equiv 1 \bmod 3$ then $M_{l}$ splits in $\mathbb{Q}(\sqrt{13})$. But we also want that the primes above $M_{l}$, say $\pi$ and $\bar{\pi}$, split in $H(K)$. Because $H(K)$ over $\mathbb{Q}$ is Galois we have: $M_{l}$ splits in $H(K)$ if and only if $l \equiv 1 \bmod 3$ and both equivalence relations $x^{2} \equiv-\left(\frac{1 \pm \sqrt{13}}{2}\right) \bmod \pi$ have solutions. A homomorphism from $\mathbb{Z}[\sqrt{13}]$ to $\mathbb{F}_{2^{l}-1}$ has as kernel $\pi$ or $\bar{\pi}$. The element $\sqrt{13}$ can be mapped to $\pm x$, with $x^{2} \equiv 13 \bmod M_{l}$. So $-\frac{1 \pm \sqrt{13}}{2}$ will be mapped to $-\frac{1 \pm x}{2}$, no matter which map we choose. It follows that $x^{2} \equiv-\left(\frac{1 \pm \sqrt{13}}{2}\right) \bmod \pi$ have solutions is equivalent with $\left(\frac{-\frac{1+x}{2}}{M_{i}}\right)=1$. Since $\left(\frac{-\frac{1-x}{2}}{M_{l}}\right)\left(\frac{-\frac{1+x}{2}}{M_{i}}\right)=\left(\frac{-3}{M_{l}}\right)=\left(\frac{M_{l}}{3}\right)=1$ if and only if $l \equiv 1 \bmod 3$, we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{39}$ represents $M_{l}$ if and only if

$$
l \equiv 1 \bmod 3 \wedge\left(\frac{-1+\sqrt{13}}{M_{l}}\right)=1
$$

Note that $\sqrt{13} \in \mathbb{F}_{M_{l}}$ since $l \equiv 1 \bmod 3$ implies $\left(\frac{13}{M_{l}}\right)=1$.
The case $d=43$.
Take $d=43$. Then $h_{K}=1$ and 2 is inert in $K=\mathbb{Q}(\sqrt{-43})$. Using the same arguments as with $d=11$ we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{43}$ represents $M_{l}$ if and only if

$$
l \equiv \pm 1, \pm 2 \bmod 7 \wedge \exists x \in \mathbb{Z} \text { with } x^{3}+x^{2}-x-3 \equiv 0 \bmod M_{l}
$$

The case $d=46$.
Take $d=46$. Then $\mathrm{Cl}(K)$ is the cyclic group with four elements, $K=\mathbb{Q}(\sqrt{-46})$. Clearly $\sqrt{2} \in H(K)$ so we can use proposition (3.9). So we already have: Suppose that $M_{l}$ is a Mersenne prime then $F_{46}$ represents $M_{l}$ if

$$
l \equiv 1 \bmod 11 .
$$

We will construct the two distinct conjugated subfields of $H(K)$ containing $\mathbb{Q}(\sqrt{2})$. With the proof of proposition (3.8) in mind we need to find two polynomials in $\mathbb{Q}(\sqrt{2})[x]$ such that the product of there discriminants is -23 . Take $f_{1}(x)=x^{2}+(1-\sqrt{2}) x+(-1+\sqrt{2})$ and $f_{2}(x)=x^{2}+(1+\sqrt{2}) x+(-1-\sqrt{2})$. Now $\Delta\left(f_{1}\right) \Delta\left(f_{2}\right)=(7-6 \sqrt{2})(7+6 \sqrt{2})=-23$. We know that $M_{l}=x^{2}+46 \cdot y^{2}$ if and only if $M_{l}$ splits completely in $H(K)$. Clearly $M_{l}$ splits in $\mathbb{Q}(\sqrt{2})$, say $M_{l}=\pi \bar{\pi}$. Because $H(K)$ over $\mathbb{Q}$ is Galois we have: $M_{l}=x^{2}+46 \cdot y^{2}$ if and only if $\pi$ and $\bar{\pi}$ split in $J_{1}$ and $J_{2}\left(J_{1}\right.$ and $J_{2}$ the two field extensions of $\mathbb{Q}(\sqrt{2})$ corresponding to $f_{1}$ and $f_{2}$ ) if and only if both equivalence relations $x^{2} \equiv 7 \pm 6 \sqrt{2} \bmod \pi$ have solutions. A homomorphism from $\mathbb{Z}[\sqrt{2}]$ to $\mathbb{F}_{2^{i}-1}$ has as kernel $\pi$ or $\bar{\pi}$. The element $\sqrt{2}$ can be mapped to $\pm 2^{\frac{l+1}{2}}$. The element $7 \pm 6 \sqrt{2}$ will be mapped to $7 \pm 6 \cdot 2^{\frac{i+1}{2}}$, no matter which map we choose. It follows that $x^{2} \equiv 7 \pm 6 \sqrt{2} \bmod \pi$
have solutions is equivalent with $\left(\frac{7 \pm 6 \cdot \frac{l+1}{2}}{M_{l}}\right)=1$. From $\left(\frac{-46}{M_{l}}\right)=1$ we get $l \equiv 1,2,5,7,8 \bmod 11($ see $d=23)$. Because $\left(\frac{-23}{M_{l}}\right)=\left(\frac{7-6 \cdot 2^{\frac{l+1}{2}}}{M_{l}}\right)\left(\frac{7+6 \cdot 2^{\frac{l+1}{2}}}{M_{l}}\right)$ we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{46}$ represents $M_{l}$ if and only if

$$
l \equiv 1,2,5,7,8 \bmod 11 \wedge l \neq 2 \wedge\left(\frac{7-6 \cdot \sqrt{2}}{M_{l}}\right)=1
$$

Note that $\sqrt{2} \in \mathbb{F}_{M_{l}}$ since $l \neq 2$ implies $\left(\frac{2}{M_{l}}\right)=1$.
The case $d=47$.
Take $d=47$. Then $h_{K}=5$ and 2 splits in $K=\mathbb{Q}(\sqrt{-47})$. In [Cohen2] page 539 we find our polynomial $f(x)=x^{5}-2 x^{4}+2 x^{3}-x^{2}+1$. Further $\left(\frac{-47}{M_{l}}\right)=1$ if and only if $l \equiv 1,2,3,6,10,12,14,15,16,18,19 \bmod 23$. Hence we get: Suppose that $M_{l}$ is a Mersenne prime then $F_{47}$ represents $M_{l}$ if and only if

$$
\begin{gathered}
l \equiv 1,2,3,6,10,12,14,15,16,18,19 \bmod 23 \wedge \\
\exists x \in \mathbb{Z} \text { with } x^{5}-2 x^{4}+2 x^{3}-x^{2}+1 \equiv 0 \bmod M_{l} .
\end{gathered}
$$

## Discussion

If we look at the numbers $\# s_{20}(d)$, for $d$ between 0 and 48 (see the table in chapter one), and the polynomials, which occur in the criteria for these $d$ 's, then it seems to be possible to predict more or less the degree of these polynomials when the numbers $\# s_{20}(d)$ are given. In the table below we compare the numbers $\# s_{20}(d)$, for $d$ between 0 and 48, and the degree of polynomials, which occur in the criteria for these $d$ 's. We have excluded all $d$ 's with $d \equiv 0,1,2,4,5 \bmod 8$. The $d$ 's and the numbers $\# s_{20}(d)$ are ordered in such a way that the first $d$ appearing corresponds with the first $\# s_{20}(d)$ appearing, the second $d$ appearing corresponds with the second $\# s_{20}(d)$ appearing, and so on.

| $d$ | degree of polynomial | $\# s_{20}(d)$ |
| :---: | :---: | :---: |
| $3,6,7,14,15,22,27,30$ | 1 | $20,19,13,12,9,8,18,9$ |
| 39,46 | 2 | 7,6 |
| $11,19,23,31,35,38,43$ | 3 | $1,2,2,5,0,2,3$ |
| 47 | 5 | 1 |

The number $\# s_{20}(31)=5$ in the table above is large compared with the other numbers $\# s_{20}(d)$ that have a polynomial degree of 3 . Of course if $d$ is a Mersenne prime then $F_{d}$ represents $d$, since $d=0^{2}+d \cdot 1^{2}$. So for $d=31$ we get the Mersenne prime $M_{5}$ in $s_{20}(31)$ for free. We also get another Mersenne prime in $s_{20}(31)$ for free, namely $M_{31}$. The following theorem, proved by Peter Stevenhagen, explains why $M_{31} \in s_{20}$ (31).

Theorem 3.11 Let $M_{l}$ be a Mersenne prime with $l \equiv 3 \bmod 4$. Then $F_{l}$ represents $M_{l}$.

## Proof:

We have $M_{3}=2^{2}+3 \cdot 1^{2}$, so we may assume that $l \neq 3$. Because $M_{l}$ is prime we have $l$ is prime. Let $\zeta_{l}$ be a primitive $l^{\text {th }}$ root of unity. Let $S=\mathbb{Q}\left(\zeta_{l}\right)$ and let $K=\mathbb{Q}(\sqrt{-l})$. We know that there is only one prime, namely $l$, of $\mathbb{Z}$ that ramifies in $S$, and it is totally ramified (see [Lang] page 73). The Galois group of $S$ over $\mathbb{Q}$ is isomorphic to $\mathbb{Z} /(l-1) \mathbb{Z}$, hence $S$ contains a unique quadratic extension of $\mathbb{Q}$. The discriminant of this extension over $\mathbb{Q}$ can only be divisible by $l$. Since $l \equiv 3 \bmod 4$ we get $K \subset S$. The minimal polynomial of $\zeta_{l}$ over $\mathbb{Q}$ is

$$
f(x)=\frac{x^{l}-1}{x-1}=\prod_{i=1}^{l-1} x-\zeta_{l}^{i}
$$

So $M_{l}=f(2)$ is equal to the norm $N_{S / \mathbb{Q}}\left(2-\zeta_{l}\right)$. Hence we have $M_{l} \mathbb{Z}_{K}=\pi \bar{\pi}$ with let's say $\pi=\left(N_{S / K}\left(2-\zeta_{l}\right)\right)$ and $\left.\bar{\pi}=\left(\overline{N_{S / K}\left(2-\zeta_{l}\right.}\right)\right)$. From

$$
N_{S / K}\left(2-\zeta_{l}\right) \equiv N_{S / K}\left(\zeta_{l}\right) \equiv \zeta_{l}^{i} \bmod 2 \mathbb{Z}_{K}
$$

for a certain integer $i$ and the fact that $K$ does not contain any $l^{\text {th }}$ root of unity unequal to 1 (here we use $l \neq 3$ ), we get $N_{S / K}\left(2-\zeta_{l}\right) \equiv 1 \bmod 2 \mathbb{Z}_{K}$. And since $\mathbb{Z}[\sqrt{-l}]=\mathbb{Z}+2 \mathbb{Z}_{K}$ we get $N_{S / K}\left(2-\zeta_{l}\right) \in \mathbb{Z}[\sqrt{-l}]$. With the same argument we see $\overline{N_{S / K}\left(2-\zeta_{l}\right)} \in \mathbb{Z}[\sqrt{-l}]$. Hence we have $x, y \in \mathbb{Z}$ with

$$
M_{l} \mathbb{Z}_{K}=\pi \bar{\pi}=\left(x^{2}+l \cdot y^{2}\right)
$$

We conclude that $F_{l}$ represents $M_{l}$. This completes the proof.

## Chapter 4

## Main theorem

In this chapter we will prove the main theorem. It will be an consequence of the following theorem.

Theorem 4.1 Let $d \equiv 7 \bmod 24$ be a squarefree positive integer. Suppose that there exists a cyclic extension $H_{4}$ of $S=\mathbb{Q}(\sqrt{-2 \cdot d})$, with $\left[H_{4}: S\right]=4, H_{4} \subset$ $H(S)$ and $\sqrt{2} \in H_{4}$. Let $M_{l}=2^{l}-1$ be a Mersenne prime. Suppose that $l>3$ and $l \equiv 1 \bmod 2 n$, where $n$ is equal to the order of 2 in the group $(\mathbb{Z} / d)^{*}$. Suppose that $(x, y)$ is the $F_{d}$-solution of $M_{l}$ then $8 \mid x$.

## Proof:

From theorem (3.5) we know that the Galois group of $H_{4} / \mathbb{Q}$ is the dihedral group with 8 elements. After we have calculated some discriminants we get the following diagram.

The numbers between the field extensions are the relative discriminants. With $K=\mathbb{Q}(\sqrt{-d}), S=\mathbb{Q}(\sqrt{(-d) 2}), J=\mathbb{Q}(\sqrt{2}), \omega=\frac{1+\sqrt{-d}}{2}, \bar{\omega}=\frac{1-\sqrt{-d}}{2}$. Note that 2 splits in $K$ as $(2, \omega)(2, \bar{\omega})$.
Now we will calculate the relative discriminants.
All the discriminants of the subfields of $J K$ are easy to be found. Using theorem (2.3) on the extensions $K \subset J K \subset H_{4}$, we get $\Delta\left(H_{4} / K\right)=8^{2}$. Also from theorem (2.3) we know that $\Delta\left(K_{i} / K\right) \mid 8^{2}$ for $i \in\{1,2\}$. Suppose that $\Delta\left(K_{1} / K\right)$
and $\Delta\left(K_{2} / K\right)$ aren't coprime then there is a prime $\pi$ of $K$ dividing both discriminants. But $\pi$ will also divide $\Delta(J K / K)$, so the inertia field of a prime in $M$ above $\pi$ will be $K$. This means that $\pi$ has ramification index 4 in $M$, which cannot be the case, cause $\Delta(M / J K)=1$. So $\Delta\left(K_{1} / K\right)$ and $\Delta\left(K_{2} / K\right)$ are coprime. Now we can use theorem (2.4). We get $\Delta\left(K_{1} / K\right) \cdot \Delta\left(K_{2} / K\right)=8$. But since they were coprime and $K_{1}$ and $K_{2}$ are conjugated, we have $\Delta\left(K_{1} / K\right)=(2, \omega)^{3}$ and $\Delta\left(K_{2} / K\right)=(2, \bar{\omega})^{3}$. Let $\Delta=\Delta\left(K_{1} / K\right)$.

Now using theorem 2.10 we have the surjective homomorphism:

$$
\mathrm{Cl}_{\Delta}(K) \rightarrow \operatorname{Gal}\left(K_{2} / K\right) .
$$

The group $P_{K}(\Delta) / P_{K, 1}(\Delta)$ is a subgroup of $\mathrm{Cl}_{\Delta}(K)$ and contains the principal prime ideal $\pi=(x+\sqrt{-d} \cdot y)$ of $K$. Because $d \equiv 1 \bmod 3$ we have that the prime 3 of $\mathbb{Q}$ is inert in $J$ and $K$ and splits in $S$, so the decomposition field of a prime $\beta$ in $H_{4}$ above 3 is $S$. We conclude that the prime $3 \mathbb{Z}_{K}$ of $K$ doesn't split in $K_{1}$. And therefore $P_{K}(\Delta) / P_{K, 1}(\Delta)$ maps surjective on $\operatorname{Gal}\left(K_{1} / K\right)$. Clearly the map from $\left(\mathbb{Z}_{K} / \Delta\right)^{*}$ to $P_{K}(\Delta) / P_{K, 1}(\Delta)$ is surjective. The group $\left(\mathbb{Z}_{K} / \Delta\right)^{*}$ is isomorphic to the group $(\mathbb{Z} / 8 \mathbb{Z})^{*}$. To see this, note that $(2, \omega)^{3}(2, \bar{\omega})^{3}=(8)$. Now we have the following group homomorphisms:

$$
(\mathbb{Z} / 8 \mathbb{Z})^{*} \cong\left(\mathbb{Z}_{K} / \Delta\right)^{*} \rightarrow P_{K}(\Delta) / P_{K, 1}(\Delta) \rightarrow \operatorname{Gal}\left(K_{1} / K\right)
$$

Because $(\alpha)=(-\alpha)$, it follows that $\{ \pm 1\}$ is contained in the kernel of the first arrow. But $\#\left((\mathbb{Z} / 8)^{*}\right)=4=\#\left(\left(\mathbb{Z}_{K} / \Delta\right)^{*}\right)$ and the first arrow is surjective, so the kernel of the first arrow equals $\{ \pm 1\}$. Therefore $P_{K}(\Delta) / P_{K, 1}(\Delta)$ has two elements. So:

$$
(\mathbb{Z} / 8 \mathbb{Z})^{*} \cong\left(\mathbb{Z}_{K} / \Delta\right)^{*} \rightarrow P_{K}(\Delta) / P_{K, 1}(\Delta) \cong \operatorname{Gal}\left(K_{1} / K\right)
$$

We know from proposition (3.8) that $M_{l}$ is completely split in $H_{4}$, so $\left(\frac{(\pi)}{K_{1} / K}\right)=$ $e$. Hence we get that $\pi=(x+y \sqrt{-d})$ is the identity element in $P_{K}(\Delta) / P_{K, 1}(\Delta)$, thus $x+y \sqrt{-d} \equiv \pm 1 \bmod \Delta$. Because $d \equiv-1 \bmod 8$ we see using proposition (1.1) that $4 \mid x$. We have assumed that $l>3$, so $M_{l} \equiv-1 \equiv x^{2}+d \cdot y^{2} \bmod 32$. But since $4 \mid x$ we have

$$
\begin{gathered}
d \cdot y^{2} \equiv-1 \bmod 16 \Rightarrow(y \cdot \sqrt{-d})^{2} \equiv 1 \bmod 16 \Rightarrow \\
y \cdot \sqrt{-d} \equiv \pm 1 \bmod 8 \Rightarrow y \cdot \sqrt{-d} \equiv \pm 1 \bmod \Delta .
\end{gathered}
$$

Using the isomorphism $(\mathbb{Z} / 8 \mathbb{Z})^{*} \cong\left(\mathbb{Z}_{K} /(\Delta)^{*}\right.$ we see that there is $\epsilon \in\{ \pm 1\}$ such that $x \pm 1 \equiv \epsilon \bmod 8$. We know that $4 \mid x$, hence $8 \mid x$. This completes the proof.

To prove the main theorem we have to construct the field $H_{4}$.
Theorem 4.2 Let $d=2^{n}-1$ be a squarefree integer with $2 \nmid n$. Let $M_{l}$ be a Mersenne prime with $l \equiv 1 \bmod n$. Suppose that $(x, y)$ is the $F_{d}$-solution of $M_{L}$ then $8 \mid x$.

## Proof

The case $n=1$ gives $d=1$ and by proposition (1.1) we have no solution. If we take $n=3$ then we take $H_{4}=H(\mathbb{Q}(\sqrt{-14}))$, because $\mathrm{Cl}(\mathbb{Q}(\sqrt{-14}))$ is the cyclic group with four elements, and use theorem (4.1).

Now we may assume that $n>3$. We only need to check that we can satisfy the assumptions of theorem (4.1). From $d=2^{n}-1$ and $n>3$ we get $d \equiv-1 \bmod 8$ and $l>3$. And from $d=2^{n}-1$ and $2 \nmid n$ we get $d \equiv 1 \bmod 3$. The order of 2 in $\left(\mathbb{Z} /\left(2^{n}-1\right)\right)^{*}$ is $n$ and also $2 \nmid n$ so we have $l \equiv 1 \bmod 2 n$. We only need to prove that $H_{4}$ exist. We will construct $H_{4}$. First we will build up the following field diagram and calculate the relative discriminant between the fields. Our result will be:

With $\alpha=1+\sqrt{2}^{n}, \bar{\alpha}=1-\sqrt{2}^{n}, M=\mathbb{Q}(\sqrt{\alpha}, \sqrt{\alpha}), J=\mathbb{Q}(\sqrt{2}), S=\mathbb{Q}(\sqrt{(-d) 2})$, $J_{1}=J(\sqrt{\alpha}), J_{2}=J(\sqrt{\bar{\alpha}}), \omega=\frac{1+\sqrt{-d}}{2}, \bar{\omega}=\frac{1-\sqrt{-d}}{2}, K=\mathbb{Q}(\omega), K_{1}=K(\sqrt{\omega})$ and $K_{2}=K(\sqrt{\bar{\omega}})$.
Now we construct this field diagram.
Take $K=\mathbb{Q}(\omega)$, with $\omega=\frac{1+\sqrt{-d}}{2}$. This is an extension of $\mathbb{Q}$ with discriminant $-d$, cause $d \equiv 1 \bmod 4$ and $d$ is squarefree. Now we make $K_{1}=K(\sqrt{\omega})$. The norm of $\omega$ equals $\frac{d+1}{4}=2^{n-2}$. Because $2^{n-2}$ is not a square we see that $K_{1}$ is a quadratic extension of $K$. The element $\sqrt{\omega}$ is a root of the polynomial $f(x)=x^{4}-x^{2}+2^{n-2}$, hence $f(x)$ is irreducible. But also $\bar{\omega}$ is a root of $f(x)$, so $K_{2}$ is also quadratic extension of $K$. All the roots of $f(x)$ are in the compositum of $K_{1}$ and $K_{2}$, so $N=K_{1} K_{2}$ is Galois over $\mathbb{Q}$. We have $\sqrt{\omega} \cdot \sqrt{\bar{\omega}}=\sqrt{2} \cdot 2^{(n-3) / 2}$, with $\frac{n-3}{2} \in \mathbb{N}$, cause $2 \nmid n$ and $n>4$. So we have $J=\mathbb{Q}(\sqrt{2}) \subset N$. Therefore the compositum of $J$ and $K$ is contained in $N$ and $S=\mathbb{Q}(\sqrt{(-d) 2})$ is contained in $N$. The discriminant of $J$ over $\mathbb{Q}$ equals 8 , so we know that only 2 ramifies in $J$. Now take $J_{1}=J(\sqrt{\alpha})$. Clearly there is a prime dividing $d$ which ramifies in $J_{1}$, so $J \varsubsetneqq J_{1}$. With the same argument we have $J \varsubsetneqq J_{2}$. The compositum $M=J_{1} J_{2}$ contains $\left(\frac{\sqrt{\alpha} \pm \sqrt{\alpha}}{2}\right)^{2}$, which equals $\omega$ or $\bar{\omega}$. So we get $M=N$.

All fields in the picture are now constructed. Now we will calculate the relative discriminants.
The discriminant of $S$ over $\mathbb{Q}$ equals $-d \cdot 8$. Using theorem (2.4) we find the ring of algebraic integers of $J K$. Then we see that $\mathbb{Z}_{J K}$ is a free module over $\mathbb{Z}_{J}$ and $\mathbb{Z}_{K}$. This gives us the relative discriminant of $J K$ over $K$ and the relative
discriminant of $J K$ over $J$.
The field $J$ has class number 1 . The elements $\alpha$ and $\bar{\alpha}$ are coprime in $J$, because if there were not coprime then there would exist a prime $\pi$ dividing both and also $1+\sqrt{2}^{n}+1-\sqrt{2}^{n}=2$, but this can not be the case as $\operatorname{gcd}\left(2^{n}-1,2\right)=1$. So the ramification index of a prime of $J$ in $M$ is at most 2 . From the polynomials $x^{2}-x \pm \sqrt{2}^{n-4}$, with discriminant $\alpha$ (corresponding to - ) and discriminant $\bar{\alpha}$ (corresponding to + ), we get using theorem (2.2) that $\Delta\left(J_{1} / J\right) \mid 1+\sqrt{2}^{n}$ and $\Delta\left(J_{2} / J\right) \mid 1-\sqrt{2}^{n}$. Now we see that every prime of $J$ which ramifies in $M$ will do this already in $J K$. So we have $\Delta(M / J K)=1$. Hence we can take $H_{4}=M$. This completes the proof.

The case $n=3$ is treated in a paper of H.W. Lenstra, Jr. and P. Stevenhagen (see [LenSte]). The proof above is a generalization of their idea, but the construction is distinct in the sense that it doesn't apply for $n=3$. For $n=3$ our field $M$ will be $\mathbb{Q}\left(\sqrt{-1+\sqrt{2}^{3}}, \sqrt{-1-\sqrt{2}^{3}}\right)$. If we would take that $M$, so $M=\mathbb{Q}\left(\sqrt{-1+\sqrt{2}^{n}}, \sqrt{-1-\sqrt{2}^{n}}\right)$, then 2 will totally ramify in the corresponding $J_{1}$ of $M$ if $n>3$. So we could not use theorem 2.10 with the nice discriminant $1+\sqrt{2}^{n}$ of $J_{1} / J$.

Another possible theme for further investigation is the following. We look at Mersenne primes of the form $x^{2}+d \cdot y^{2}$. More generally one might look at primes $\frac{n^{2}-1}{n-1}$ of the form $x^{2}+d \cdot y^{2}$. Such a prime splits in $\mathbb{Q}(\sqrt{n})$ as $\frac{\sqrt{n}^{2}-1}{\sqrt{n}-1} \cdot \frac{\sqrt{n}^{2}+1}{\sqrt{n}+1}$. Now one can use the argument of proposition (3.8) to prove that $\frac{n^{l}-1}{n-1}$ splits completely in the field $H_{4}$, if such a field exists. With the same kind of arguments used in the proof of theorem (4.1) one might be able to prove that $x$ (or $y)$ is always in the same congruence class modulo $\Delta(\mathbb{Q}(\sqrt{n}) / \mathbb{Q})$.
